The steam plant of the Dominion Power & Transmission Company, located just outside the city limits of Hamilton, on the shores of Burlington Bay, has now been operating for over a year and in point of efficiency is more than meeting the strict specifications laid down for it by its designers. By its dependability it has also demonstrated, in a general way, the soundness of the argument that where conditions of use are such that the customer is prepared to pay for a more perfect service, the hydro-electric plant supplemented by the

furnaces, industrial plants operated electrically and involving a large amount of labor, electric cooking in the home and so on, then it is easily seen that the small added cost of a continuous service may be offset many times by the losses entailed by one or two protracted delays. This is a point frequently lost sight of by customers in making comparison between rates in various cities or rates charged for various operations or by competing companies. There is as much difference, generally speaking, between the different kinds

Fig. 1. The steam-electric plant of the Dominion Power and Transmission Co. as it will look when completed

steam plant frequently offers the only solution. Where the load is purely a lighting proposition it is not, of course, a matter of such supreme importance that short shutdowns should be guarded against, but where it is a matter of dollars and cents or where great inconvenience is caused by power delays, such as, for example, in the operation of electric

of service rendered by different systems as there is between any other two things we buy. It follows, naturally, therefore, that the cheapest is not always the best.

The plant is situated just outside the eastern limits of the city of Hamilton, Canada, on the southern shores of Burlington Bay. It is designed for an ultimate capacity of 75,000

Fig. 2.—General arrangement of plant. From right to left, coal, boilers, steam plant, electrical equipment

kv.a., 25,000 kv.a. of which has been installed at date of writing. The station forms part of the system of the Dominion Power & Transmission Company, and delivers its output at 44,000 volts to the high tension lines of the company. In addition to its generating capacity the station is designed to act as a stepdown transformer station of 25,000 kv.a. capacity to transform the high tension current to 13,200 volts for distribution to local factories in the manufacturing district located in the near vicinity. 12,500 kv.a. of this stepdown capacity has been installed at the time of writing.

The general arrangement of the plant as shown in diagram, Fig. 2, is very largely responsible for the very efficient figures of operation which this plant has shown. The coal is taken from storage yards (see Fig. 1), or direct from trains and deposited over the crusher hopper into auxiliary storage in the coal building shown at the extreme right of the diagram. The coal is crushed as required, and elevated by means of bucket conveyor to the storage bunkers above the boilers shown in the diagram. A weighing larry distributes the fuel from these bunkers to the stokers.

The coal handling plant has a capacity of 60 tons per hour. The feeder is a steel cased double plunger with opening 26 in. x 30 in. Coal is moved by two plungers, operated by adjustable eccentrics placed one 90 deg. in advance of other. Power is provided by means of sprocket and chain drive from crusher countershaft. Clutch is furnished so feeder may be cut out and crusher driven independently. Discharge of feeder is coupled direct to top of 2 roll crusher. The crusher is a 2-roll type direct geared to 25 h.p. Westinghouse at 750 r.p.m. One roll shaft is supported on rigid, the other on adjustable bearings sliding in guides and backed up by heavy coiled springs. Rolls are set to deliver coal at 2 in. and under. Each roll consists of 2 heavy cast iron spiders supporting 6 cast steel segments. The roll shaft is 4-7/16 in. diameter. The rolls are 26 in. diameter, 24 in. long.

The elevator has a length of 38 feet centres, bucket type. The casing is 5 ft. 0 in. high by 9 ft. 0 in. wide, with ladders on either side of elevator.

The weighing larry has rail centres 21 ft.; hopper capacity 5 ton; hopper scale, 10 ton capacity, with reverse reading beam. Spouts lead from hopper for delivery to stokers with gates operated from cage. The traversing motor, direct geared to trucks, is Westinghouse slip-ring polyphase, type H.F., 5 h.p., speed 935 rp.m., 3 phase, 550 volts, 662/3 cycles.

The coal bunker has a capacity of 420 tons. It is equipped with three 18 in. x 18 in. double undercut gates operated by lever from weighing larry. Coal storage building has a capacity of 1,250 tons.

The stokers are the Taylor Stoker Company type. There are four 11 retort stokers, with width 19 ft. 6 in. and depth 8 ft. 3 1/2 in. There are 3 dampers with each stoker and each is also supplied with one side cleaning and two front observation doors. Each pair of stokers has two engines. There are two fan engines and one horizontal for each pair of boilers, two fans for each pair of boilers with two paddle wheels, capable of delivering sufficient air to operate all stokers at 150 per cent rating.

The Boilers

The water tube boilers are by the Edgemoor Iron Company. There are four 1,050 h.p. boilers, set singly. The plates are of open hearth steel. The headers are of flange steel plates,

Fig. 3.—Showing one side of Boiler Room and 5-ton coal larry.

attached to drums by flanges, expanded into inner plates of header; manholes are provided with forged steel covers. Flanged oval hand holes, fitted like manholes, are placed opposite each tube; these oval covers being inside are tightened by boiler pressure and independently removable.

The drums have an outside diameter of 35 1/8 in., length 20 ft., made of fire box steel, longitudinal seams, double butt strapped triple riveted. Each boiler has four drums of plates, 7/16 in. thick.

Each boiler has 472 Am. standard soft steel tubes, 4 in

diameter, 20 ft. long, 2 lower rows No. 9 gauge, balance No. 10. Valves and fittings are as follows:

Three $4\frac{1}{2}$ in. Ashton pop safety valves; four 2 in. Hancock feed water valves; four 2 in. Hancock check valves; two $2\frac{1}{2}$ in. Faber blowoff valves; two $2\frac{1}{2}$ in. Homestead blowoff cocks; one 12 in. Ashcroft steam gauge; one Reliance water column with water gauge and three try cocks.

The fronts are fitted with rolling tube header door. Heating surface is 10,470 sq. ft. per boiler. The weight, approximate, 150,000 lbs. each.

Four Foster superheaters are installed, guaranteed to raise the temperature of 31,500 lbs. of steam per hour, at pressure 200 lbs. per sq. in., to 5,380 F. corresponding to superheat at 150 deg. With boiler operating at 150 per cent. rating, superheat is 160 deg.

The stokers feed the boilers at a sufficient rate to force them to 235 per cent. of rating without difficulty. Fig. 3

Fig. 4.—View of 1050 h.p. Edgemoor boilers during erection.

shows a view of a portion of the boiler-room. The boilers are equipped with automatic soot blowers and the customary instruments to enable the engineers to operate the boiler intelligently. The flue gases are carried away by two radial brick chimneys.

The chimneys were built by the Canadian Kellogg Company. Dimensions:

Height above foundations, 240 ft.; internal top diameter, 12 ft.; height of base, 22 ft.; cross section of base, round in shape, 22 ft. 2 in. diameter; lining 40 ft. high from point 2 ft. below flue opening; Baffle 20 ft. high and 8 in. thick; lightning conductor 6 copper points, $\frac{3}{4}$ in. diameter, 8 ft. long, with $1\frac{1}{2}$ in. solid platinum tips. Lower ends of points connected to proper cable encircling chimney from this cable; one $\frac{7}{16}$ in. 7 strand No. 10 Stubbs gauge copper cable is carried to ground and connected to copper ground plates; one 4 in. H. & M. patent gauge and connections; one 2 in. pyrometer connection; steps of $\frac{5}{8}$ in. galvanized round iron built in on inside of chimneys, spaced 18 in. C. to C.; two cast iron cleaning doors; cement caps put on each chimney and painted two coats heavy pitch.

Water Purification

Make-up water for the plant is obtained from Burlington Bay and is successfully treated by the We-Fu-Go system of

water purification. The water softening building is shown at the left of Fig. 1.

The two reaction and settling tanks are: 24 ft. 6 in. in diameter, 19 ft. 4 in. high, dressed Washington fir, $2\frac{3}{4}$ in. thick, fitted with round steel hoops and malleable iron draw lugs. Tanks are provided with steel ladder outside and wooden ladder inside with platform at top of outside ladder, both tanks are covered. One inch pipe connection is pro-

Fig. 5.—View of eleven retort stokers during erection.

vided for drawing samples, also mercury depth gauge. Gauges and brass faucets are mounted above white enamel iron sink on enamelled plate. Electric contact alarm bell is operated by copper float; a double throw switch admits connections to either tank.

The tanks are equipped with mechanical stirring device,

Fig. 6.—Heater, feed pumps, air pump, fan engine, in pump pit.

each tank taking four hours for treatment of its capacity of water. Water is supplied to tank at rate of 60,000 U. S. gallons per hour.

The Reagent mixing tank is 3 ft. in diameter, 2 ft. high,

of 3/16 sheet steel, provided with hand operated stirring device.

The filter tanks are two in number, 8 ft. 0 in. in diameter, 5 ft. 4 in. high, inside dimensions of $2\frac{3}{4}$ in., Washington fir, round steel with hoops and malleable iron draw lugs. Cross connected, provided with galvanized iron distributing and wash water overflow trough. A filter bed of crushed quartz (98 per cent. silica) is supported by layer of washed and graded gravel. The inlet pipes are provided with brass fitted balanced valves and seamless copper floats, to regulate flow of water from settling tank, and maintain uniform level in filter. An electric alarm bell, operated by copper float rings in water softener and boiler-room.

The air wash pipes in filter bed have discharge openings equally distributed over filter bed and connected to pressure blower. The valves are controlled by numbered cast iron floor stands having extension stems where main operating valves are below floor.

Letters to the Editor

We have a letter from a well-known consulting engineer, criticising the equipment in the Brantford station, described in our last issue. We had time to pass this criticism along to Mr. Catton and also have a reply from him. Both letters follow:

Editor, Electrical News:

In looking through the May 1st number of your paper I note on page 30, the switchboard designed by Mr. Catton, and if the section of the switchboard is drawn to scale, would offer the following criticism:

The disconnecting switch below the bus bars is in a dangerous position for if an operator opened this switch by mistake when the feeder was alive he might cause a flash that would result in a short circuit on the bus bars above.

Referring to the double throw disconnecting switch above the bus bars, it appears to me that the lower switch would be very difficult to open with a hooked pole on account of its location with respect to the bus bars. A man would either have to stand on a stool or chair or else use a pole 15 feet long and at that he would be touching the bus bars with the pole, and every one knows it is very difficult to hook into an eye of a disconnecting switch with a pole longer than a few feet.

I do not consider the arrangement a good design and believe that such a design should not be submitted to the public as being something exceptionally good and thus permit others to copy same.

The type of double throw switch for throwing a feeder onto the emergency bus bar could make a lot of trouble if these two bus bars were not in synchronism,

Yours truly,

Reader.

Editor Electrical News:

In answer to your communication of the 8th inst. re criticism on switching equipment, I might say that the section drawing of board is not to scale. The spacing between bus and disconnecting switches is 13 inches.

Regarding the double throw switches we might state that they are much more easily operated than "Reader" imagines. We do not find them difficult to operate or we would have placed them higher. However, this equipment does not have to be so placed. Windsor suspends theirs from the ceiling, face of panel to the floor, but in our case the present position was the only place. I know of some very good electrical men who think this apparatus is good and are going to install it.

Regarding the synchronism of bus-bars, it was explained

that feeders were paralleled while transferring load to auxiliary bus.

We do not anticipate any of the troubles our critic has suggested because we have used the apparatus since it was installed. We have a vastly improved condition regarding flexibility.

We would like to have our critic see the equipment in the station.

Yours truly,
Brantford Hydro-electric System,
Per W. R. Catton, Superintendent.

Toronto, May 1st, 1919.

Dear Sir:—

You are hereby notified that the Annual General meeting of the Canadian Manufacturers' Association for 1919 will be held in the King Edward Hotel, Toronto, on June 10th, 11th and 12th next. Business will commence at 10.30 a.m. on June 10th.

I earnestly hope that you will make a special effort to attend in order to give the Association the benefit of your co-operation and advice in solving the difficult problems which are now confronting the manufacturers of this country.

The Association is now entering what may be described as the third period of its history. During the first period, from 1872 to 1899, its activities were provincial and its membership limited to about 300. During the second period, from 1899, when it was organized as a National Association to the signing of the armistice, the membership increased from about 300 to nearly 3,500, and branches were organized from coast to coast. The second period saw a great growth of manufacturing. The present period, beginning with the signing of the armistice, will be the period of readjustment from war to peace conditions, the continued and rapid development of Canada as a nation, and I hope and believe, a corresponding development in the activities of the Association and in the increase of its membership.

Three of the most important matters for discussion at the Annual Meeting are (1) the readjustment of the existing relations between employers and employees, (2) the revision of the tariff and (3) the development of export trade. In addition, there will be report of the various committees which, during the past year, have dealt with an unusually large number of subjects of vital importance to Canadian manufacturers. It is from the views and decisions of the members present at the Annual Meeting that the policy of the Association for the coming year is largely shaped.

The programme outlining the business to be transacted will be mailed to you in due course. I appeal to you to make a special effort to be present.

Anticipating the pleasure of meeting you in Toronto on the above dates, I remain,

Yours faithfully,

W. J. Bulman,

President.

The Tungar Rectifier—Its Theory, Characteristics and Application—II.

By Mr. F. Keith D'Alton

In preceding paragraphs (in our issue of May 1st) the underlying principles of the Tungar Rectifier were dealt with, and the marketed production of the manufacturer was described in more or less detail. The performance of the simple single phase rectifier as sold will now be outlined and in addition, the various advantages of different possible combinations of two or more single phase rectifiers will be presented and discussed.

One Half Wave Rectification

A rectifier containing only one bulb and designed to give only one half of the supply wave in the rectified voltage and current, is termed a "One Half Wave" Rectifier.

In Fig. 11 are shown the connections of the bulb and auto-transformer which go to make up the one-half wave rectifier. The auto-transformer, designed to operate on 115 volts, a.c.

Fig. 11.—Connections of one rectifier for one-half wave rectification.

(frequency considered) has two taps at 26.6 and 28.6 volts respectively, from one end. The small 2 volts part of the winding between these taps has sufficient current capacity to carry the filament current continuously. It may be noted that one lead from the supply runs through and forms the positive terminal of the rectifier secondary (d.c.).

As to the bulb, it has a filament designed to operate at 2 volts with a current of about 20 amperes. The filament is made of fairly large dimensions in order to have a long life; it being found that the action of the electrons causes a disintegration of the tungsten metal.

When the tube is cold it refuses to allow current to pass through it in either direction, but when the filament is heated current may then pass downward through the bulbs (from graphite to tungsten filament).

The voltage from one end of the auto-transformer winding to the nearest tap will be 26.6 volts, (root-mean-square

value) and the peak value of this will be in the neighborhood of 37.7 volts. Comparing Figs. 2 and 3, we find that the peak value of the rectified wave, on no load, is approximately the same as the peak value of the tap voltage. This is not sur-

Fig. 12.—(above)—Rectified voltage and current, single-phase—One-half wave, full load, non-inductive.

Fig. 13.—Rectified voltage and current, full load, inductive.

Fig. 14.—(below)—Rectified voltage, storage battery voltage and current while charging storage batteries.

prising since there is an insignificant drop in the bulb when no current is flowing.

The voltage wave of Fig. 3, with peak value of 37.7 volts will cause a moving vane a.c. voltmeter to indicate 16.8 volts,

Fig. 15—Single rectifier characteristics. Voltmeter indications and Form-factor

while a permanent magnet type of d.c. voltmeter indicates 10.0 volts. The form factor undoubtedly is 1.68 in this case; and since this is greater than the form factor of a half sine wave, it indicates that the rectified wave is more peaked or

narrower at the base. By observation, we find this to be the case.

The load on the rectifier is connected in as shown in Fig. 11, having due regard for polarity, if the load is such that it becomes necessary to consider polarity.

Different load conditions give different effects. For example, Fig. 12 shows voltage and current waves when the load is non-inductive; the current and voltage (by d.c. instru-

Fig. 16—Characteristic curves—One Rectifier giving one-half wave rectification

ments) were respectively 6 amperes and 7.7 volts. It will be seen that these waves are of the same shape and "in phase" with each other.

If now the non-inductive load be replaced by a load which is highly inductive, the voltage and current waves take the forms shown in Fig. 13. The current starts with the rise of voltage in the direction which can start current through the tube, but, like all currents, through inductive resistances it returns to zero lagging behind the voltage, but not reversing. That part of the voltage wave marked "Inductive Voltage" is not due to the rectifier, but is caused entirely in the

Fig. 17—Connections of two rectifiers for two-half wave rectification.

inductance of the load as the current dies down. Even after the current reaches zero, there is some residual flux in the iron of the inductive load and this flux, in dying down, causes a gradually reducing voltage.

When a storage battery load is connected to the rectifier we find that current only flows at the times when the rectified voltage is higher than the battery voltage, Fig. 14. In this oscillogram, the waves are not on the same base line. The

matter of battery charging will be dealt with more fully in later paragraphs.

Considering the characteristics of the one half wave rectifier as a unit, we find that the drop in voltage under load is proportional to the load current, Fig. 15. Apparently the impedance of the auto transformer and resistance in the bulb are the cause of this, and act in the same manner and proportions as if this size of rectifier had an ohmic resistance of 0.7 ohms.

Fig. 15 also shows the relative values of the indications of the a.c. and d.c. voltmeters and also a slight variation in form factor. As the form factor gradually reduces (as the load increases above 1.5 amps) from 1.77 to 1.55 we judge that there is a step toward the ideal d.c. condition but the approach is not very close.

In Fig. 16 are shown the operating characteristics of the one-half-wave rectifier. The curve showing "power factor" applies only on the supply side of the rectifier and at a time when a non-inductive load is connected to the load terminals. The impressed voltage is alternating, and the primary current, though also alternating, has a wave form which is not symmetrical with regard to its zero line. Here "power factor" is taken as the result of dividing "Input watts" by the product of impresser voltage and primary current as read by a.c. instruments. This method, though standard and correct if the voltage and current waves be both of sine form, is in this case questionable as to its meaning and accuracy. It is,

Fig. 18 (above)—Rectified voltage—Single Phase—Two-half wave—No load

Fig. 19 (below)—Rectified volts and current, two-half wave—Single phase, full load—non-inductive.

however, a method well understood and as used here to show that the primary current increases more rapidly than the load current.

As seen from Fig. 11, there is no method available for regulating the voltage but it may be noted that the rectifier will, in a sense, automatically regulate the current reducing it as the voltage increases, and can be used in a practical way to charge any battery having a voltage less than 20 volts. From 20 volts up to the maximum, 37.7 volts, the charging is too slow a process to be used.

The rectifier is automatic when an interruption of power occurs. The filament simply cools down and the battery cannot discharge. When the power is again turned on, the filament heats up again and the rectifier picks up its load.

Two-Half Wave Rectification

Although the simple rectifier, as placed on the market, is intended for one-half wave rectification only, it is very satisfactory to connect two rectifiers, according to Fig. 17, and supply them with power at 230 volts, single phase.

We then get a rectified voltage (at no load) with twice as many peaks as given by one rectifier, Fig. 18 illustrates the point; the peaks are the same shape and in consequence the a.c. voltmeter indicates 1.414 times the indication of the half wave voltage while the d.c. voltmeter indicates just twice the value it indicated on a half wave.

While the peak values are the same, we see that the form

factor for this two half wave voltage is 1.15, a marked reduction from that obtained by a one half wave rectifier.

When a resistance load is now attached, Fig. 19, the voltage drops slightly, the current wave has the same shape as the voltage wave and the form factor suffers no appreciable change no matter what the value of the load. Fig. 20 shows the form factor as a straight line and also shows the indications of a.c. and d.c. voltmeters. A comparison of Figs. 15 and 20 shows that the readings of a.c. and d.c. instruments are closer together at all loads with two rectifiers than with one. Hence the two half waves rectifier is a closer approach to d.c. conditions.

Fig. 16 may be considered to apply to this connection also, except that the load current would be multiplied by two. The power factor and efficiency are not in any way improved.

Three Phase Balanced Star Connection

A study of Fig. 11 will reveal the fact that three rectifiers may be connected in star on a balanced three phase circuit as shown in Fig. 21, in which case the supply voltage must be $\sqrt{3} \times 115$ volts, or 200 volts, 3 phase.

Since we have exciting currents and unsymmetrical waves to handle, the branch voltage will depart from the pure sine form and appear as shown on the oscillogram, Fig. 22. In the different phases these voltage waves will be similar but displaced by 120 degrees from each other. The rectified no-

Fig. 20—Voltmeter indications and Form Factor. Two half-wave Rectification.

load voltage will have three peaks per a.c. cycle and appears as shown, Fig. 23.

There can be no interchange of current on account of the valve action of each bulb. Hence the bulbs will work satisfactorily together even though they be on different phases.

This connection gives a decided improvement in form factor over either of the connections previously discussed, as it reduces that ratio to 1.08 (at one quarter of normal load). It will be observed that the waves just touch the zero line.

As non-inductive load is applied, the peaks drop a little and the base of the wave rises from the zero line, Fig. 24. We are now approaching still closer to the direct current ideal conditions. As the load increases the form factor drops, rather quickly at first, and later more gradually, Fig. 25, until a value of 1.04 is reached.

Running under the above conditions it may happen that one or even two of the bulbs may burn out. A bulb may become inoperative. If so, it is usually on account of the wearing out of the filament.

When one bulb burns out the voltage and current waves

assume the shape shown in Fig. 26. When two bulbs burn out at the same time, the voltage and current are both very materially reduced on account of the impedance of the two phases without load, and the respective waves are as shown in Fig. 27.

Fig. 28, the voltage and current from this three phase con-

Fig. 21—Three-phase star connection giving three peaks (d.c.) per cycle of a.c. supply.

nection with an inductive load, shows us a still better form factor as the ripple is reduced in amplitude, being farther from the base line.

Considering the characteristics of this three phase combination, Fig. 29, we see that the efficiency and power factor are

Fig. 22 (above)—Branch 3-ph. unrectified voltage at no load.

Fig. 23—Rectified voltage, 3-ph. star connection—No load.

Fig. 24 (below)—Rectified voltage and current, 3-ph. star connection—Full load, non-inductive.

not in any way improvements on the single phase half wave rectifier. The good factor, then, is the chief advantage.

Six Phase Balanced Diametrical Connection

Going one step farther and using six rectifiers on a six phase circuit, Fig. 30, we get a still further reduction in form factor, bringing it down to the value 1.01. Our voltage wave

Fig. 25—Voltmeter indications and form-factor

at no load contains only the crests of the six peaks per a.c. cycle, Fig. 31. These ripples are made of still less importance under load, bringing the form factor at full load to a value of 1.005 as in Fig. 32. This is a decidedly close approach to a smooth direct current.

The efficiency and power-factor are not any improvement on the simple half-wave rectifier.

APPLICATIONS OF THE RECTIFIER

Having now fully discussed the theory, and possible connections and combinations of Tungsar rectifiers, it seems ad-

Fig. 26 (above)—Rectified voltage and current—3-ph. star—Failure of one bulb.

Fig. 27—Rectified voltage and current—3-ph. star—Failure of two bulbs, Fig. 28 (below)—Rectified voltage and current—3-ph. star—Full load, inductive.

visible to consider some of the uses to which this device may be applied.

Storage Battery Charging

First in importance among the various uses of the Tungsar rectifier is the charging of storage batteries from an alternating current supply. The requirements of such a battery in charging are two-fold, that the supply voltage be higher than the battery voltage, and that there be no reversal of current. Pulsations of current are not objectionable for this class of work and it is therefore not necessary to have a good form-factor.

When a single phase, half wave rectifier is charging a storage battery, we get voltage and current as already shown in Fig. 14. It is only that part of the rectified voltage wave which is above the storage battery voltage that is in any way effective in causing current to flow. As the circuit is non-inductive, the current wave must agree with the effective part of the voltage wave. As the storage battery volts increase the current flow diminishes. In this way the rectifier is self-regulating.

For a given battery voltage, up to the maximum of 37.7 volts, there is a corresponding effective charging value to the rectifier voltage. The curve, marked "one half wave" in Fig.

Fig. 29—Characteristic curves with three rectifiers—3-ph. connection.

33 gives this effective charging value for the complete range of battery voltage.

Care must be exercised to obtain correct polarity in connecting in a battery.

It may be of interest to some readers to make a small calculation on the time required to charge a certain set of storage batteries. It is taken for granted that the reader realizes that the voltage of the battery rises while charging and, for simplicity in calculation, we will let the **average** value of battery voltage be represented by V .

Let R be the resistance in ohms of the battery as connected and let T be the time in hours for charging.

The resistance of the rectifier may be taken as 0.7 ohms. It is obvious that, as already mentioned, the rate of charging a battery of 20 volts is much slower than with one of 5 volts, not only because the resistance of the 20 volt battery is liable to be higher but the value of the rectified volts in excess of battery volts will be less.

In Fig. 33 are given two curves, one for a single rectifier, Fig. 11, and one for three rectifiers in balanced star connection, Fig. 21. The values of K and K' referring respectively to

the one phase and three phase systems, are the effective charging values of the rectified voltage waves.

The effective charging current, I , with one rectifier will be expressed as follows—

$$I = \frac{K}{R + 0.7}$$

Let $A H$ = ampere hours required by one cell.

$$\text{Then the time, } T = \frac{A H}{K} \times (R + 0.7)$$

The number of ampere hours necessary to charge a cell, (or, the ampere hours a cell is capable of delivering) is usually specified on the cell. It should here be understood by the reader that the time will be divided by two if two rectifiers be used as in Fig. 17 connection and that K is replaced by K'

Fig. 30—6-ph. diametrical connection of six half wave rectifiers, giving six peaks (d.c.) per a.c. cycle

if three rectifiers be used as in Fig. 21 connection, giving waves as shown in Fig 34.

A question has frequently been asked regarding the time lag of the charging current after the rectified voltage has begun to rise above the battery voltage. Experiment has shown that this lag is in the neighborhood of $1/5000$ of one second and hence insignificant.

As before mentioned the rectifier is automatic and the battery may be left to charge during the night, no harm re-

Other Practical Applications

The Tungar bulb has other uses than working as a rectifier.

In the modern radio-telephone aeroplane set a bulb built on the same principle as the Tungar bulb, is used to control the voltage of the wind-driven generator on the aeroplane. The requirements of this generator are that it produce a con-

stant voltage through a large range in speed, i.e., 4,000—14,000 r.p.m. The bulb employed acts on the differential field winding of this generator, and is found to be quite capable of producing the required steadiness in voltage.

In the University of Toronto, Department of Physics, the bulb has been used to give an alternating current of high fre-

Fig. 31 (above)—Rectified voltage—6-phase Diametrical—No load.
Fig. 32 (below)—Rectified voltage and current—6-phase—Non-inductive load.

quency when supplied with power by direct current. The energy in this alternating current is very small.

The unidirectional current produced as a rectifier may be used for magnetizing magnets, controlling d.c. relays, contactors, and many other devices where the pulsations will not cause trouble.

With the introduction of a "grid," that is a perforated metal electrode between the filament and graphite anode, the bulb becomes an amplifier of oscillations. In this state it is an essential part of the modern telephone repeater, and of both transmitting and receiving apparatus in the radio telephone.

Measurement of Resistance

It may be not a little surprising to the reader to learn that this pulsating current may be used to accurately measure the

Fig. 33—Effective charging values of rectified voltage waves of one-half wave and 3-ph. connection. K =one-half wave. K' =3-ph. connection.

ohmic resistance of any circuit, even though the circuit be highly inductive. It is, nevertheless, a fact, provided direct current instruments be used.

Firstly, with non-inductive circuit, the current waves and voltage waves are identical in shape, hence,—

Voltage drop

———— = resistance in ohms.

Current in amps.

For this either one, two, three or six rectifiers may be used.

Secondly, with a highly inductive circuit, the three phase three rectifier scheme is used, Fig. 21. Then the ripples in

current are rounded off, taking a shape closely approximating a sine wave. For purposes of calculation, let us assume that the ripple is a sine wave; it will have three times the frequency of the a.c. supply.

In Fig. 35 we have two waves plotted, the upper being voltage, the lower being current, through an inductive resistance. In the oscillogram, Fig. 36, the actual current wave is shown. Now, the current, apparently, consists of the sum of two currents, namely a direct current of value I and a ripple of 3 times normal frequency and of amplitude C .

This current passing through an inductive resistance, induces a voltage as shown by the upper wave, Fig. 33, in which V is the voltage due to the current component I passing through the ohmic resistance, and the superimposed sine wave of amplitude e is due to the current ripple alone passing through both resistance and inductance of the circuit.

The direct current permanent magnet instrument reads the average of a ripple plus any positive unvarying unidirectional current. The average of the ripple lies along the straight line marking off the limit of I (or, in the case of voltage, the line marking off the limit of V). If then the d.c. voltmeter reads V , and the ammeter reads I . The value of

$$\frac{\text{voltmeter reading } V}{\text{ammeter reading } I} = \frac{V}{I} = \text{ohmic resistance.}$$

The ripple is automatically entirely eliminated with each instrument.

Mathematically, it can quite simply be proven that the above holds for any case where the ripple is symmetrical about its zero line, independent of its shape or frequency.

This, then is a finer work to which the Tungar rectifier may be applied, and in which results, as checked by actual test, are very satisfactory.

Protection

In Fig. 11, it will be seen that one primary lead runs through to form one of the secondary leads; in Figs. 18, 21,

Fig. 34 (above)—Rectified volts, storage battery volts and charging current—Three phase star connection.

Fig. 35 (below)—Rectified volts and current through inductive resistance; plotted, for purposes of calculation, with sine wave ripple.

and 30, leads from points on the primary winding form secondary positive leads. The question of protection, therefore, presents itself.

To handle leads from an underground service transformer is, at all times, dangerous, and particularly so if the operator's hands be wet. In using the tungar rectifier (with auto-transformer) ordinary care must be exercised but when charging storage batteries where the operator is liable to

have wet hands and, perhaps, be standing uninsulated from the ground, special care is necessary.

The rectifier is a low voltage device, but it should not be confused with other low voltage appliances which draw their power from a strictly low voltage source. Provided

Fig. 36.—Actual current through highly inductive load from three rectifiers, star connected. The straight line is the zero line of current.

the insulation of the supply circuit is good the rectifier is perfectly safe, but when some defect develops in the supply system there is a certain amount of danger.

After a long illness, Mr. Duncan McDonald, former manager of Montreal Tramways, and inventor of the p.a.y.e. car, died at St. Agathe. He was born at St. Thomas, P.Q., and in his early years was a driver of the old horse cars in Montreal. In 1886 he went to St. Paul and Minneapolis and secured a practical knowledge of the operation of electrical railways. On returning to Montreal he became superintendent of the Street Railway Co., and later went to Paris as engineer and managing director of 500 miles of lines in and around that city. He again came to Canada, and was appointed general manager of the Montreal Tramways Co., a position he resigned in 1912. Mr. McDonald served as controller for the city for two years. He was a member of the Institute of Civil Engineers of France, and of the Institute of Electrical Engineers of Great Britain.

The Principles Underlying Radio Communication—Radio Pamphlet No. 40, issued by the Signal Corps of the United States army. This book points out briefly the basic facts and principles of electro-magnetism and their application to radio communication. These topics are presented in a simple manner so that students with very little mathematical preparation may understand them. Frequent references to standard books are given so that further study may be made of the subject if necessary. The following chapter headings will indicate the scope of the work: (1) Elementary electricity; (2) Dynamo electric machinery; (3) Radio circuits; (4) Electro-magnetic waves; (5) Apparatus for transmission and reception, exclusive of vacuum tubes; (6) Vacuum tubes in radio communication. Bound in stiff, imitation-leather covers, size 4½ in. x 7 in.; 350 pages; 55c a copy.

The Contractor-Dealer

Industrial Illumination—Good Lighting is not an Expense—It is an "Investment" and Yields Big Dividends.

By Mr. Otis L. Johnson*

Illumination, as it applies to industry, has, with the help of science and art, made great strides in recent years.

To-day manufacturing interests everywhere are looking to it to gain assistance in an earnest endeavor to increase production, decrease spoilage, decrease cost, and prevent accident.

Industrial illumination is so important that three states in the United States have already passed lighting legislation; one of these is now drafting more stringent regulations and two other states are now holding public hearings of their tentative Lighting Codes. The fact that five states now recognize the importance of good lighting shows conclusively that other states will follow, and before many years all states in which a large amount of manufacturing is done will also pass laws to protect the employees and aid the employer.

Better factory lighting is needed because it will increase production, decrease costs, improve quality, reduce spoilage, prevent accidents.

In other words, it will conserve the human material in industry—its most valuable asset.

The average time of use of artificial lighting in factories is three hours per day. Unless the working conditions under artificial lighting approximate closely those of daylight, early morning and late evening hours, to say nothing of the loss caused by forcing night shifts to work under poor artificial lighting, all have their effect upon production.

Blindfold a skilled mechanic. How much work can he do? Provide him with poor light and he is able to do some work, but in order that this skilled mechanic may work efficiently and economically he must be provided with the right amount of the proper kind of light.

Light is a tool. Who could expect a workman to properly perform his tasks with poor tools? A man and his machine are a combination, and as such must work together harmoniously. Machine and workman may be the best that money can buy, but poor lighting handicaps the workman; therefore the combination cannot work at highest efficiency.

Furthermore, working conditions have their bearing upon home life. Cheerful, contented workmen carry that spirit home, while a man made grouchy by headaches from eye strain produced by glaring light sources, is very apt to encounter domestic difficulties. When this happens the man cannot go back to work the next day in the proper frame of mind to work at highest efficiency. Here again the manufacturer loses by not providing a properly designed system of illumination. Good lighting makes more cheerful workmen, who labor at increased efficiency because they are better able to see the task they are performing, and because of good light they have more inclination to do good work. All of this tends toward the increased production which is so important at this critical period, and which every manufacturer is trying to obtain.

Improved quality and decreased cost per unit of output

is just as important as increased production. It will not be denied that a workman can produce better goods when he is able to see distinctly and with comfort the piece upon which he is working. Spoilage means a heavy dollars and cents loss. It means the loss of raw material and also the cost of labor uselessly expended. A few years ago a United States census report stated that out of \$150,000,000 spoilage in the United States during the year, \$28,000,000 was due to poor light. The amount would be larger now on account of the increase of production in the last few years, but the ratio would be at least as great.

Accidents cause suffering; they also cause loss of time already paid for by the employer; they lessen production; and many accidents are demoralizing to the entire working force. The employer bears the brunt of most of this loss, and also the loss due to the compensation which must be paid to the injured workman. **Seventy-five per cent. of industrial accidents occur during hours of darkness or semi-darkness; more than one-fourth of these can be prevented by the installation of properly designed lighting systems.** It is the duty of every manufacturing institution to provide artificial illumination which will prevent expensive and distressing accidents. This is not an academic question. These statements are conservative when viewed in the light of the facts as they are reported by eminent investigators and supported by repeated and authentic experiments.

The result of increased production, improved quality, decreased cost and fewer accidents is larger dividends. It is the prime purpose of every plant to earn as much profit as possible; in fact, that is the reason for its existence; therefore, the manufacturer who neglects to furnish dividend producing illumination is taking hard cold cash out of his own pocket to pay for his negligence. It is not possible to lay down definite rules by means of which proper lighting could be installed to cover all conditions, but certain fundamental principles may be stated, principles found in all good lighting.

These are: Correct intensity, good diffusion, light from proper direction, absence of drop cords, absence of glare (both direct and reflected).

In all lighting legislation which has been enacted the amount of light or intensity has been stated as a part of the law. No one who had given the matter any thought at all would expect a piece of work to be performed economically and efficiently under 25 per cent. or even 50 per cent. of the correct amount of light.

The National Electric Light Association, the Society for Electrical Development, lamp manufacturers and reflector manufacturers, all publish authoritative tables which give the correct intensity of illumination. These tables usually refer to the kind of industry, the character of work, and give the correct amount of light necessary under average conditions. Of course, it must be understood that colors of machinery, walls, posts, etc., affect the intensity, and if these are dark, lamps of greater wattage must be installed to obtain the correct illumination.

The elimination of sharp, contrasting shadows is important. This is accomplished by means of diffusion, and can be brought about in several ways, such as; the use of large reflecting surfaces; designing a system so designed that

*Illuminating Engineer Benjamin Electric Mfg. Co., Chicago

the light from many reflectors falls on the spot in question; the obstructing of the direct rays of light by means of some opaque or translucent material.

It does not require argument to convince anyone that a workman cannot work efficiently when standing in his own light. For this reason it is highly desirable so to locate lighting units that no matter where machines or benches are located they will receive light from the proper direction. The proper location of light sources will have the effect of eliminating undesirable shadows.

Drop cord or localized lighting must be used sometimes, but the need for it is so small as to be almost negligible. Its advantages are very few and unimportant, while its disadvantages are so numerous and important that the first should be given little consideration.

Guard the Eyesight

The workman should not be allowed to control the position of the light or lights near him for the reason that he does not usually understand or believe that incorrect light can damage his eyesight, and the time that he occupies in adjusting his light is unnecessary because he does not understand what to do. It is therefore wasted time from the standpoint of the employer.

An important argument against the drop cord or localized system of lighting is glare. Glare has been described as "Light out of place." It can and does do more harm than any other part of a poorly designed system of lighting. Glare must be avoided, for the safety of the eyes is as important as the safety of limb. The danger of mechanical injury to the eyes is recognized by most employers and employees, but very few are aware of the harm done by poor lighting.

Impairment of vision is a slow process, and it may take months or even years before the individual is aware of it. Nevertheless, while the impairment is taking place, he is suffering ocular discomfort and his efficiency in his work is decreasing. A great many workmen seem to be drawn toward bright lights and they act as if they believed that the more light they allow to strike their eyes the more they have on their work. This, of course, is not true. Even when reflectors are provided for drop cords (which is infrequent) the workman usually adjusts it so that the light strikes his eye, and even if he does protect his own eyes the chances are very strong that he forgets the man near him and so arranges the light that it enters this other workman's eyes.

Under the factory conditions mentioned above, we have somewhat the same effect when the light is so situated that it shines directly into the eyes of the workman. When a bright light is held continuously in the line of vision, it tires the eyes just as the glare from snow on a sunny day half blinds one. In order to rest the eye, the workman will turn his head toward a spot which is not so highly illuminated. After he does this the muscles in the eye relax and allow the pupil to enlarge. The workman then bends again to his task, whereupon the pupils contract on account of the glare.

This process may be repeated again and again with the ultimate effect that he has greatly reduced ability to see clearly. There is a conscious or unconscious effort to obtain clearer vision. When this effort is maintained for some hours it unfailingly results in great eye fatigue and with it comes a general indisposition to work, with a possible chance for severe headache.

Certainly no one can expect that workmen can be efficient under the conditions we have described. Aside from the question of efficiency and production, which are desirable things for the manager of an industry, it is far from

humane to force the workman to strain his eyes, and jeopardize his usefulness and health, under such conditions.

By carefully designing the lighting system so that all these principles are correctly involved the resultant illumination will increase production, improve quality, decrease cost, prevent accidents, and result in an improved morale.

Glare may not only be obviated, but be controlled by the use of reflectors, just as the nozzle of a hose controls the flow of water. The shape of the distributor of light depends upon the finish of the reflector, and upon the position of the lamp filament relative to the reflecting surface. The reflecting surfaces usually employed in factory lighting are:

Porcelain Enamel

For general all-round efficiency and economy the porcelain enameled surface is best. Its initial cost is more, but its cost of maintenance and upkeep are less than any of the other finishes; therefore, it is cheapest in the end. It does not discolor or blister because of heat; it is restored to initial efficiency by cleaning; it is impervious to gas, smoke or acid fumes. Being practically opal glass fused upon steel, it has to be treated with some care, because abuse will chip it. Light reflected from this surface is largely diffused.

The mechanical strength of porcelain enamel depends upon the ingredients which go into the making of it. Enamel can be manufactured which has a very high reflecting power, because it is very white, but the enamel will chip easily on account of its brittleness. Enamel which has a distinctive bluish color has a low reflecting efficiency, but it is tough. The enamel which is used on our reflectors is compounded so that it gives the maximum reflecting efficiency consistent with the toughness of the enamel.

Paint Enamel

The distribution of light about paint enamel, when new, is practically the same as that of porcelain enamel. It does not resist smoke, gas or acid fumes; it discolors on account of the heat of the Mazda "C" lamp, and the dirt rubs into it instead of off, when an attempt is made to clean it. For this reason it has to be repainted frequently, thus making it expensive in the long run.

Matt Aluminum

Light can be controlled by means of aluminized reflectors much more readily than with either the porcelain or paint enamel, and in some places this type of reflector has to be used in order to obtain the proper distribution of light, but all the disadvantages named against paint enamel apply to this matt aluminum surface, and make it expensive in the end.

Mirrored

Mirrored glass reflectors are far from economical for industrial lighting. The mirrored surface is on the back of a glass form, and the light from the lamp has to pass through this same layer of glass before it is projected to the working plane. Even when the reflectors are new there are two absorptions of light on account of two thicknesses of glass. Heat and age cause this glass to cloud, a condition which results in more absorption.

Then, when the reflectors become dirty, light has to pass through a layer of dirt and a layer of clouded glass to the reflecting surface. Then it has to penetrate back through a layer of clouded glass and a layer of dirt on the return trip. It is easily seen that the absorption in this case would be high. Glass reflectors are, of course, easily broken and the reflecting surface peels off, hence the upkeep expense of this type of lighting would be exorbitant.

Mirrored reflectors are usually deep, and the claim is made that they hood the lamp. In other words, the angle of cut-off is large, but the boosters of this type of lighting

equipment have failed to recognize the fact that the mirrored surface back of the lamp is almost as bright as the filament itself; therefore, the angle of cut-off is small.

The proper reflector and lamp to fit the conditions that exist on each individual job when used according to the fundamental principles of illumination will result in:

- (a) Reduced eyestrain;
- (b) More cheerful surroundings;
- (c) Less fatigue in performing work;
- (d) Better order and neatness in shop;
- (e) More effective superintendence and management.
- (f) Approximately 12 per cent. increase in production;
- (g) Approximately 25 per cent. reduction in preventable accidents.

The cost of installation and up-keep of a properly designed lighting system is extremely low when one considers the benefits. This cost amounts to approximately 1 per cent. of the average workman's wage. This is insignificant when compared with the extra dividends of increased production. The cost of spoilage and accidents should be added to the lighting bill of the poorly lighted plant, and then the difference in first and up-keep costs of the good and bad systems are in favor of the properly designed system.

Good lighting is not an expense, but instead, is an investment which pays large dividends.

How I Increased My Sales 100%

The eternal household question is that of "servants" More and more it is becoming apparent that the average home must do without them and in proportion as the human race resigns itself to this condition it comes to realize that the next best thing is "electric service." Of course it doesn't exactly mind the children while the mother attends the afternoon tea or theatre performance, but aside from that, generally speaking, what doesn't it do? And even the electric housewife leaves her children at home alone with a much easier conscience knowing that the chances of mishap are minimized by the absence of poisonous gases and matches.

And now as a substitute for that "rara avis," the sewlady, the sew-motor is coming forward and saying "Just a little pressure with the foot and I'll do the rest. And you won't need to wait for me three weeks before I can give you a day or half-day—as a special favor." Just at the moment it looks as if this sew-motor will become almost as popular as the electric iron and special sale campaigns are yielding very satisfactory results. Such a campaign is outlined below. It is described by the Society for Electrical Development as follows:

How One Dealer Does It

Perhaps the best way to point the way to sew-motor selling is to tell how one dealer does it. This dealer picked a well-known make, enlisted the full co-operation of the progressive manufacturer and jobber, and set a definite time for his campaign—one week. He called it "Sewing Economy Week" at —, and laid out his campaign about on this basis:

First:—Being experienced, he planned his campaign down to the smallest detail before setting it in operation. He placed a sewing machine in his window, connected up with a sew motor and ready to run.

Then he carefully explained the operation of the sewing machine and sew motor to his errand boy, a bright youth in knickers. And he persuaded him to agree to sit in the window and operate the equipment.

Near the machine he placed a 40-watt lamp arranged

so that its light was reflected upon the machine and the boy. From the lamp he suspended a placard which read:

The Sew Motor uses just as little current as this 40-watt lamp—they're both economical."

On the background of the window appeared a large placard reading:

"Even 'mere' man can sew the sew-motor way —Look! It's Easy—Comfortable—Cheap! Sews ¼-million stitches for one cent. Come in!—Miss Worth will tell you all about it!"

The boy was supplied with a series of cards which from time to time he held up and prompted observers to read. [Note: A girl will do as well, and placards can be changed accordingly.]

Among the cards were some which stated facts and figures showing the advantages and economies of Sew-Motor-ing.

But realizing that a boy could go to lengths that would be in bad taste for an adult, he took advantage of the opportunity to make the display distinctive by injecting a little humor into it. He supplied the boy with some cards in a lighter vein and that were to be interspersed with the showing of the more matter-of-fact ones. They read:

"If you must pedal, get a bicycle. But when you sew—well, come in and Miss Worth will show you an easier way."

"If I can do it, think what you girls could do! It takes us men to find the easy way. Come in and Miss Worth will tell you all about the sew motor"

Sister Susie says she won't marry her beau unless he promises to get her a Sew Motor. She's smart. But it's never too late to get a Sew Motor. Come in and ask Miss Worth."

"Women do grow older—but those who sew the Sew Motor way never look old or tired. Want to stay young? Come in."

Second: A section of the store was screened off and equipped to suggest a sewing room. The demonstration was in charge of a capable woman operator.

Third: A series of advertisements was planned, featuring the demonstration and inviting housewives to bring their sewing to the store and have it done the Sew Motor way.

Fourth: A girl was set to work getting the names, addresses and telephone numbers of housewives from the telephone directory, classifying them according to streets.

Fifth: A saleswoman was secured who had a good telephone voice—clear, well modulated and with a "smile" in it. Then she was drilled in a neat telephone solicitation designed along lines laid down in the Society's Special Service entitled, "How to Promote Business by Telephone."

Sixth: Anticipating that not all women who received a telephone invitation to bring some sewing to the store and have it done the Sew Motor way would be able to do so, arrangements were made to have a salesman display the motor to all such housewives in their homes.

Then, having everything provided for, the campaign was begun.

Advertising Arguments

Among the arguments used in his advertisements were these:

Inherent disadvantages of ordinary sewing machine for the housewife in the small apartment: Foot work is necessary to operate the needle and the machine is nearly always in the way.

Reasons why women buy the portable electric machine:

- (1) "I can put it away out of sight. (2) I can move it myself from room to room. (3) It is such a convenience to be

able to sew where the light is good in any room." (4) The health reason: "My doctor won't let me run my old machine any more."

Old machines have been given to the Red Cross and they in turn buy motors to operate them. Thousands of garments were turned out of Red Cross rooms with no fatigue to workers.

Selling points: "There is nothing mysterious about the little Sew Motor which does all the hard work. There is no confusion, no having to remember this or that; it is the way the old machine has always been controlled only the treadle now is a sort of foot rest. Hands do the same thing they always did. They guide the work, nothing else. The motor does it all."

With an electric sewing machine, four times as many garments can be made with less fatigue—as treading is eliminated. The electric sewing machine makes 800 to 1,200 stitches a minute—works four times as fast as a good operator using a foot powered machine.

Going away in the summer, it is possible to check the portable electric sewing machine the same as other baggage and have the machine to use during the summer at hotel or country place. It can be taken about in an automobile, if desired.

A motor for the old machine is one of the greatest household helps designed to bring comfort to the housewife. A big day's sewing can be done in a few hours without fatigue. She can sew by the window, outdoors on the porch in summer, by the fireside in winter, wherever there is an available socket.

Farm Labor—His Problem and Your Opportunity

By Fred B. Raymond*

When the short-sighted business man reads in his evening paper that wheat is selling at more than \$2 a bushel, he groans because the price of bread is high.

When a far-sighted business man reads about the 1,000,000,000 bushel crop of \$2 wheat, he begins to figure out what he can sell to the farmers who have all this money in their pockets.

As a class, the richest people in Canada today are the farmers, and they are going to get richer each year for the next five years (barring serious crop failure) because it is going to take five years to get the world back to normal agricultural production.

But with all their prosperity, our farmers face a great and growing problem—the problem of labor. How will that problem be solved?

Obviously by labor-saving machinery, by the farm tractor and the farm electric power plant.

The first of these solves the labor problems of the field—the plowing, harrowing, seeding, cultivating and reaping.

The second solves the labor problem of the home and farm buildings—the washing, ironing, separating, churning, grinding, feed cutting, wood sawing, pumping, threshing, stacking, repair-shop work, and the thousand and one chores formerly done by the housewife and the hired help.

Nothing can be plainer or more obvious than these two facts. The farmer must have labor-saving equipment, and he has the money to pay for it.

What are you going to do about it? Are you going to sell farm power plants? Or are you going to complain that agents who do sell them are "stealing" your business? Are you going to reach outside your town limits for farm-wiring business? Or are you going to allow someone else to have it—or worse, allow the farmer to put in his own equipment?

Are you going to advertise and sell appliances suitable for farm use? Or are you going to literally force the farmer to buy appliances from peddlers or by mail? It's up to you.

Many men commit the error of thinking that a dealer must be in a "farming community" to sell goods to farmers. This is only half true.

Within an hour's automobile ride of any of our largest cities there are many hundreds of farms that cannot be served by central stations.

Nose around a bit and you will find a big prosperous farm implement concern in every metropolitan centre.

Go deeper and you will find an up-and-doing tractor agent with probably more business than he can take care of.

Pick up the telephone directory and you will locate the man who is getting rich right now by selling farm power plants.

The modern farmer doesn't hitch up the old gray mare to a springboard and drive to some little crossroads community twice a season—not any more. He slides in behind the wheel of an auto and honks to the big city at least once a week.

They come by hundreds into any centre you may mention—by auto, by interurban trolley and by train.

Without doubt perhaps the most important and timely message to the electrical trade can be summed up thus:

The farmers need farm power plants, wiring, accessories and appliances, because farm labor is their problem.

They have the money in pocket to pay for them.

They do not necessarily restrict their purchasing to rural communities, nor to agents who drive to their doors.

They are, as a class, ready to do business on a business basis with anyone who earnestly and intelligently tries to do business with them.

Farm power plant selling is not what even an enthusiast would call easy. It takes brains, equipment and the hardest kind of work.

Farm wiring jobs do not wander into your shop unchaperoned. They must be fished for with the right bait and tackle. Incidentally, the man who seeks such business must consider carefully what policies will win the co-operation of agents who are selling plants and who consequently control many of the wiring contracts.

Farm appliance business is not non-competitive. Low-voltage flatirons, incandescent lamps, vacuum cleaners and the rest are peddled through the country from flivvers and are delivered by parcel post on every rural mail route.

Do these difficulties, does this competition, discourage you?

Then do not complain of agents and the catalog houses, If they are smart enough and aggressive enough to get the business, and if the electrical trade cannot grasp the opportunity, it is our own fault.

Meter with Cast Winding

A new type of rotor with cast winding which has been recently designed by the General Electric Company, Schenectady, N. Y., presents new features and improvements worthy of brief description. The bars and short-circuiting rings comprising the windings employ the same material and are cast in a single operation. With the windings thus made a solid unit, rigidity, durability, and better balance are procured. The cast winding from an electrical point of view also insures uniform cross section and union between the bars and the end rings. This has become a factor in eliminating operating difficulties due to open-circuiting of joints between bars and rings. Holes bored radially through the cast end rings give effective ventilation for rotation in either direction. The new cast winding rotor is said to be especially effective on induction motors of the "Squirrel cage" type.

Lincoln Arc Welder

The larger cut of the two shown herewith is a reproduction of a photograph of a gasoline-driven welder, handled by the Lincoln Electric Co. The engine is a four cylinder Winton, with automatic speed control, and the generator is the regular type, as furnished on Lincoln Electric Arc Welders, which supplies a direct current available from 50 to 150 amperes with an available voltage of from 50 to 15. This particular machine is carried on a Chalmers

The Lincoln Welder at Work

Truck and represents part of this company's equipment for doing ordinary work, such as repairs to boilers, tanks, etc. This picture was taken just previous to the outfit leaving under its own motive power for Port Dalhousie for use on government barges. The smaller picture shows the machine after it was unloaded from the truck and at work. For a short job the truck would be run right up to the work and the job completed without unloading the Welder.

Hamilton Electrical Association

The Hamilton electrical contractors and dealers held another of their successful meetings on Wednesday evening, May 7th, in the Royal Connaught, the president, Mr. Stalford, in the chair. The chief business of the evening was a discussion of the question of forming a branch of the recently formed Ontario Association and the final vote was unanimous in favor of this course.

Mr. Kenneth A. McIntyre, president of the Toronto branch of the Ontario Association of Electrical Contractors and Dealers and provisional chairman of the Ontario Association, along with the executive of the Toronto Association, was present to take part in the discussion. Mr. McIntyre explained at length the scheme of provincial organizations, which consists in dividing the province into about seventeen districts. Each district will elect a representative to the provincial executive which in turn will elect a president who may or may not be one of these elected members. The Ontario Organization will thus operate under an executive control of a president and seventeen executive members.

The outlines of the district of Hamilton were discussed at this meeting and, subject to arrangement of minor details, were arranged. Transportation facilities and inspection boundaries are two factors that must influence decision in this matter.

The members at the meeting also discussed with the Toronto members the advisability of adopting the Open Price Plan of exchanging tenders. The Toronto members explained the working of the system as they had found it to date. A committee was finally named to make arrangements to set the plan in operation not later than June 1st.

The Conference Committee of the Hamilton Association recommended that the working rules be adopted and become effective on May 1st, 1919. In accordance with the working rules, a conference committee and the members of the joint examining board were appointed.

A number of members of the Brantford Association were present to take part in the discussion, including the presi-

Lincoln Electric Welder ready to move under own motive power.

dent, Mr. Henderson. At his invitation Mr. McIntyre will go down to Brantford in a few days to discuss with the Association there the advisability of making Brantford the centre of another district—which will elect a representative to the Ontario executive. It is expected too that the Brantford members will adopt the Open Price Plan.

Toronto Contractors' Monthly Meeting

The Toronto electrical contractors held their regular monthly meeting in the King Edward Hotel on Friday evening, May 8. The chief item of business consisted of a discussion with Mr. Gunn, representing the Labor Union, of the standard of wage during the coming year. During the past couple of years the contractors have been endeavoring to build up a spirit of co-operation between the employer and employee, and it was the understanding that Mr. Gunn would come to this meeting prepared to discuss ways and means in an effort to arrive at an amicable basis satisfactory to the workman and the contractor alike. It came as rather a shock, therefore, that Mr. Gunn presented an ultimatum of 75 cents or strike. It is unfortunate that the Labor Union has taken this uncompromising attitude. If they are in the right they had nothing to gain by it, as an open discussion would have proven this fact. At the moment it looks as if it would take some time before the two parties could establish themselves again on the friendly relations existing in the recent past.

Mr. Gunn was somewhat late in arriving and in the interval discussions centered around the open price plan. Mr. McIntyre, the president, announced that a meeting of the members who are operating on this plan would be called in the near future.

The Booth-Hall Company, designers and builders of electric furnaces, announce the removal of their executive and sales offices to Room 1007-1008 Hearst Building, 226 West Madison Street, Chicago. This change was necessitated by new arrangements made in connection with the manufacture of their electric furnace equipment. Increased facilities for turning out standardized furnace equipment have been provided with a large manufacturing company located in Chicago.

The Van Dorn & Dutton Company, Cleveland, Ohio, manufacturers of gears, have opened branch offices at New York and Chicago. At both cities it is their purpose to specialize in gears and pinions for electrical work. Mr. Harry F. Keegan, formerly with the Chicago surface lines and well known in the electrical railway field, will manage the Chicago branch with offices at 1241 First National Bank Bldg. His brother, Mr. John Keegan, who will manage the New York end, with offices at Room 317, 30 Church St., comes from the Interboro Railway.

The Ohio Brass Company have sent out announcements of a change in their Chicago office, in effect May 1, 1919. The new office will be at 1217 Fisher Bldg., 343 South Dearborn St.

The Canadian Drill & Electric Box Company have just installed a well equipped galvanizing plant. It is the intention to have all their products galvanized so that they will withstand acid and other deteriorating agents. The process has been approved by the Hydro-electric Power Commission.

A newspaper report states that a complete automatic telephone system is contemplated for the city of London, England, the cost to be in the neighborhood of \$35,000,000.

Agency for Condor Lamps

W. A. Hall & Co., 164 King St. W., have taken over the agency for Condor lamps.

Personal

Mr. C. H. Keeling, District Sales Manager of the Square D Company, has just returned from a six weeks' trip covering Western Canada through to the Coast. Mr. Keeling states that he saw evidence on all sides that electrical contractors throughout the West have greatly improved their merchandising policies. He noticed a marked change in the way of clean windows, finer window displays and neater stores.

Mr. L. M. Cochrane, who has been associated with the Northern Electric Company Limited, in Calgary and Winnipeg for the past eight years, has resigned his position of District Sales Manager of the Winnipeg district, to enter into business for himself. Mr. Cochrane is opening a sales office in Winnipeg which will be his headquarters, and will represent manufacturers of electrical and automobile accessory products. He will cover the western territory from Port Arthur and Fort William to the Pacific Coast, and will work with jobbers and distributors exclusively. Mr. Cochrane is visiting manufacturers in Eastern Canada and the United States completing arrangements in connection with his business, and expects to open his office about June 15th.

Mr. Edgar T. Driver, who recently arrived from England on the C. P. R. steamship "Melita" to take up a position in the Toronto office of the British Aluminium Company Ltd., is a graduate in electrical engineering of the Northampton Engineering College in London. Not only does he hold the E. E. degree of this college but also the B. Sc. honors degree of

London University. Mr. Driver is the author of one or two treatises on dynamo and motor design but more latterly has been making a special study of transmission line conductors and his name will be familiar to readers of the "Electrical News" as the author of several articles on the subject with special reference to the characteristics of aluminium and aluminium-steel cables. For the last few years he has been serving with the Royal Air Force in France but has been demobilized in time to take part in the increased commercial activity of the British Aluminium Company and is joining their Canadian Head Office as technical expert.

Current News and Notes

Marysville, N. B.

The town council of Marysville, N. B., have under consideration the construction of a transmission line approximately 9 miles long. It is understood the material will be purchased and work done by the town.

Montreal, Que.

It is announced that the Shawinigan Water & Power Company will open an office in London, England, for the further sale of the products of their subsidiary companies.

The name of the Crown Electric & Supply Company, Montreal, has been changed to the Montreal Crown Electric & Supply Company. Mr. Wm. Flood is the proprietor.

Morden, Man.

The ratepayers of Morden, Man., by a vote of 71 to 7, passed a by-law authorizing an expenditure of \$15,000 for improvements to the lighting system.

Ottawa, Ont.

The Central Electric Supply Company have opened a branch in Ottawa under the name of The Bank Electric Supply Company.

Penticton, B. C.

An electric railway is being spoken of between Penticton, B. C., and Oroville, Wash., a distance of about fifty miles. Power for the line would be secured from the West Kootenay Power Company.

Port Elgin, Ont.

The Associated Municipalities of Northwestern Ontario is the name of a new organization formed at Port Elgin for the purpose of endeavoring to secure a supply of Hydro power in a territory some 75 miles in length comprising 33 municipalities. This district extends from Southamptton to Wingham and across to Mildmay. Delegates from the various municipalities were called to Port Elgin by the Board of Trade.

Teck Township, Ont.

A by-law was submitted on May 9th on the question of building a transmission line through Teck Township to secure a supply of power from the Northern Ontario Light & Power Company of Timmins, Ont.

Toronto, Ont.

The council of the city of Toronto have rescinded their action of last year in giving notice to the Toronto Electric Light Company that on the expiration of their franchise the city would exercise the right to purchase the company's holdings.

Winnipeg, Man.

The Manitoba Electrical Association was recently formed for the purpose of boosting the electric idea. The officers are: Mr. G. L. Guy, of the Manitoba Public Utilities Commission, president; Mr. J. M. Leamy, provincial electrician, vice-president and Mr. M. E. Deering, of the Northern Electric Company, secretary-treasurer.

Trade Publications

Plugs and Receptacles—Folder by the Harvey Hubbell Company of Canada, illustrating various types of their standard products.

The Electrical Alloy Company, Morristown, N. J., are distributing Catalogue No. 9, describing resistance materials and Grade "A" "Monel" metal; pure nickel, spark-point nickel, wire, ribbon, strip, rods and all other electrical alloys manufactured by this company. Mr. A. D. Stevenson, formerly with the Northern Electric Co., sales manager of the company, is covering Canada regularly.

Manufacturer of Alternating Current motors wishes active representation in Toronto and vicinity. Box 936, Electrical News, Toronto. 10

WANTED

A practical Electrician, capable of adjusting and repairing motors and domestic appliances. A good chance for advancement. Address, 10t.f.

HYDRO ELECTRIC COMMISSION,
St. Thomas, Ont.

Central Station Promotes House-Wiring Campaign

The Public Service Co., of Northern Illinois, is exerting every effort to stimulate activity in the wiring of houses located in its territory. This company serves a rather prosperous district in northern Illinois including the suburbs of Chicago and, although the percentage of houses wired in this district is much higher than the average, it is expected that through the efforts of the company and the co-operation of the local contractors the number will be materially increased.

The company for some time has had a two-year time payment plan for wiring in effect and has been co-operating with the contractors by allowing them to take contracts on this basis and purchasing such contracts from them. During the campaign this plan will be given wide publicity. In addition, in those parts of its territory where the company does not maintain a construction department, solicitors will be engaged to canvass the locality for the local contractors.

In the April Sales Bulletin of the company the importance of providing adequate electrical installations is strongly urged. Comparing the modern house-

wiring installations with the automobile refinement, it states: "If the public knew no more about automobile refinements than it does about electrical conveniences, automobiles would be sold minus lamps, starters, tops, windshields and tools, and would be equipped with undersized tires and one-cylinder engines. They would run, but that's all. Most house-wiring jobs give light, but that's all."

This lack of realization of electrical refinements is laid to the fact that the customer is usually buying electrical work on a price basis only and no attempt is made to point out to him the great advantages of oversized wiring, especially feeders, plenty of flush receptacles, switches, additional and emergency lighting outlets and other electrical conveniences and seldom is informed of the advantages of the many electrical appliances. It is pointed out that electric service today means more than the lighting of the home and the company's salesmen are strongly urged to advocate the installation of these electrical convenience features and the use of electrical appliances as much as possible.—Electrical Review.

Increased Manufacture of Electric Heaters in Sweden

The use of electricity for heating purposes is comparatively new, but since the enormous water power in Sweden and Norway has been increasingly utilized, and especially because of the acute shortage of fuel during the war, electric heating has become more and more extensive in Scandinavia. Elektriska A. B. Volta was organized in Stockholm in 1915, with a capital stock of \$32,160, for the manufacture of electric heating apparatus. In the beginning this factory employed 40 men, but at the end of 1917 the number had increased to 500.—Electrical Review.

World's Smallest Turbine

What is believed to be the smallest operating turbine ever built has been completed by Ivan T. Nedland, Hillsboro, N.D. Mr. Nedland also built the smallest electric motor and the smallest steam engine in the world, these being on exhibition at the Panama Canal Exposition in San Francisco and also at the University of North Dakota. The turbine is smaller than either of the other small devices. The rotor is made of steel and has six slots. The diameter of the rotor is 0.032 in. and the shaft is 0.007 in. in diameter. The weight of the rotor is 2 mg. The diameter of the com-

plete turbine is 0.048 in., or about one-half the diameter of an ordinary pin head. The complete turbine weighs 12 mg. The turbine will not run with steam as that fluid is too heavy for it to heavy for it to operate on. It is mounted on a hollow pedestal so that an air hose can be attached to the bottom. It will run at very high speed when air is applied. The casing of the turbine is made of gold. The complete machine consists of eight parts. It is kept in a glass case so that moisture, which would affect its running, will be excluded.—Electrical World.

Electric Heaters For Railroad Tracks

During the heavy snowfall last winter a somewhat novel form of electric heater was devised for use on certain British railways for keeping the points and switches free from frozen snow and ice. The heaters consisted of a length of resistance wire wound on a porcelain tube. This latter was centered between insulating disks and placed in lengths of 2½-in gas pipe. These tubes were about 1½' in length, and these somewhat rough and ready heaters were coupled up to lengths of ordinary rubber-covered wire and laid under the points to be protected. As soon as the current was switched on the snow naturally began to thaw and very satisfactory results were obtained.

Similar heaters have been in use on railroads in this country for some years, being brought out for service when snow begins to fall. The heaters take 11 amperes at about 36 volts, and for ordinary work they are used three in series across a 110-volt circuit. It has been found necessary to use 18 heaters for the turn-outs, and these simple but efficient appliances have been employed in large numbers under pipe runs, near signal mechanism and in the vicinity of the gearing for turn-table pits.—Electrical Review.

Electrical Books—Special Prices

The following Books are Offered Subject to Previous Sale:

- "American Electricians' Handbook, a reference book for practical electrical workers, by Terrell Croft. 712 pages, with over 900 illustrations. Published by McGraw-Hill Book Co., Price \$3.00.
- A Handbook on the Steam Engine, by Herman Haeder. Published in 1914 by Crosby, Lockwood & Son. 522 pages, illustrated. Price \$3.00.
- A Laboratory Manual of Alternating Currents, by John H. Morecroft, E.C. Published in 1912 by Renouf Publishing Company. 248 pages, illustrated. Price \$2.00.
- Baudot Printing Telegraph System, by H. W. Pendry. Published in 1913 by Whittaker & Company. 144 pages, illustrated. Price \$1.00.
- "Central Stations," by Terrell Croft, 1st edition published in 1917, by McGraw-Hill Book Co., Inc. 332 pages, illustrated. Price \$2.50.
- Direct-Acting Steam Pumps, by Frank F. Nickel. Published in 1915 by McGraw-Hill Book Company. 258 pages, illustrated. Price \$3.00.
- Direct Current Machinery, Theory and Operation of, by Cyril M. Jansky, B.S., B.A., 1st edition, just published by McGraw-Hill Co., Inc. 285 pages, illustrated. Price \$2.50.
- Dynamo-Electric Machinery, by Francis B. Crocker, E. M., Ph.D. Published in 1908 by American School of Correspondence. 236 pages, illustrated. Price \$1.00.
- Electric Arcs, by Clement D. Child, Ph.D. Published in 1913 by D. Van Nostrand Company. 194 pages, illustrated. Price \$2.00.
- Electric Car Maintenance, by Walter Jackson. Published in 1914 by McGraw-Hill Book Company. 274 pages, illustrated. Price \$2.00.
- Electric Railway, by A. Morris Buck, M. E. Published in 1915 by McGraw-Hill Book Company, Inc. 390 pages, illustrated. Price \$3.00.
- Electric Railway Engineering, by C. Francis Harding, E. E. Second Edition. Published in 1918 by McGraw-Hill Book Company. 416 pages, illustrated. Price \$3.00.
- "Electric Traction," a treatise on the application of electric power to tramways and railways, by A. T. Dover. Published in 1917 by Whittaker & Co. 661 pages with 518 illustrations and five folding plates. Price \$6.00.
- Electrical Injuries, by C. A. Lauffer, M.D., published in 1912 by John Wiley & Sons. 77 pages. Price 50 cents.
- Electro-Dynamics, by Charles Ashley Carus-Wilson. Published in 1898 by Longmans, Green & Company. 298 pages. Price 50c.
- Elementary Principles of Illumination and Artificial Lighting, by Arthur Blok, A.M.I.E.E. Published in 1914 by Scott, Greenwood & Son. 235 pages, illustrated. Price \$1.00.
- Elementary Graphic Statics, by John T. Wight. Published in 1913 by Whittaker & Company. 226 pages, illustrated. Price 75c.
- Elementary Magnetism and Electricity, by Cyril M. Jansky, B. S. Published in 1914 by McGraw-Hill Book Company. 212 pages, illustrated. Price \$1.50.
- Examples in Alternating-Currents, (Vol. 1), by F. E. Austin, B.S. Published in 1915. 223 pages, illustrated. Price \$2.00.
- Examples in Magnetism for Students of Physics and Engineering, by Prof. F. E. Austin, B. S. Published in 1916. Price \$1.00.
- First Aid in Case of Electrical Shock, by Dr. John Woodman. Published in 1908 by the New York Edison Company. Illustrated. Price 50 cents.
- "Fuel," by C. F. Herington, recently published by D. Van Nostrand Co. 211 pages, with 84 illustrations. Price \$3.00.
- Handbook of Machine Shop Electricity, by C. E. Clewell. Published in 1916 by McGraw-Hill Book Company. 461 pages, illustrated. Price \$3.00.
- How to Make High-Pressure Transformers, by Professor F. E. Austin. Second edition, just published. 48 pages, illustrated, price 65c.
- "Powdered Coal as a Fuel," by C. F. Herington, recently published by D. VanNostrand Co. 211 pages with 84 illustrations. Price \$3.00.
- Practical Electric Illumination, by Terrell Croft, First edition, published by the McGraw-Hill Book Co. 225 pages, illustrated. Price \$2.00.
- Principles of Direct Current Machines, by Alexander S. Langsdorf, M. M. E. Published in 1915 by McGraw-Hill Book Company. 404 pages, illustrated. Price \$3.00.
- Principles of Alternating Current Machinery, by Ralph R. Lawrence. Published in 1916 by McGraw-Hill Book Company. 614 pages, illustrated. Price \$4.50.
- Principles of Electrical Design—D.C. and A.C. Generators, by Alfred Still. Published in 1916 by McGraw-Hill Book Co. 365 pages, illustrated. Price \$3.00.
- Radiodynamics—The Wireless Control of Torpedoes and Other Mechanisms, by B. F. Miessner. Published in 1916 by D. Van Nostrand Company. 206 pages, 112 illustrations. Price \$2.00.
- "Radio Communication, Theory and Methods, with an appendix on Transmission over Wires," by John Mills. First edition, just published by McGraw-Hill Book Co., Inc. 205 pages illustrated. Price \$1.75.
- Radiation, Light and Illumination, by Steinmetz. Published in 1909 by McGraw-Hill Book Company. 304 pages, illustrated. Price \$2.50.

- Wray's Manual of Car Lighting. Published in 1915 by Wray Publishing Company. 340 pages, illustrated. Price \$1.50.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

Strong Selling Features of Durable Daytons Mean Real Profit for Dealers

Illustrating Durable
Dayton No. 676

Six blade 12 or 16 inch
Oscillating Fan, con-
vertible to bracket
position.

Durable Dayton Fans are easy to sell and good to sell because of their quality—they mean satisfied customers and repeat orders—Dayton fans are sturdily made, for long, untroubled service. They consume less current and their square-end blades deliver more breeze.

The line is complete, including electric ceiling, desk, and wall bracket models for alternating and direct current, exhaust fans and water motors. Easily adaptable; all Dayton desk fans can be immediately converted into the wall bracket type.

Opportunity to "Cash In"

Demand is for quality now, stronger than ever before—Daytons have held the fan quality leadership for 26 years, the best fan for every purpose.

Durable Dayton dealers are given co-operation; sales helps and advertising that brings in customers and profits.

THE NEW COMPETITION

An examination of the conditions underlying the radical change that is taking place in the commercial and industrial world—the change from a competitive to a co-operative basis.

By Arthur Jerome Eddy, Author of "The Law of Combinations" etc.

Mr. Eddy believes that a radical change is taking place in the commercial and industrial world. He preaches the same doctrine as Mr. W. L. Goodwin, the get-together doctrine. He believes that competition, as it is generally practiced, is costly in operation, and he offers some very practical and concrete suggestions, including the "open price" policy, about which we are hearing so much and which promises solution of some, at least, of the ills in our industrial life.

Mr. Eddy's book is for the man, no matter what his business in life, who has a competitor—and that includes most of us. It opens to view a "land of promise" where everybody gets a square deal and everybody knows he gets it. No man can read this book without, in some measure, having his business policy affected thereby.

Sixth revised edition, including the full texts of the Clayton and the Federal Trade Commission Laws, all important provisions of which are explained, defined and commented upon. 423 pages, including index; price \$1.60 postpaid from the

Electrical News, 347 Adelaide W., Toronto, Ont.

The Right Kind of
**ELECTRICAL
 SWITCH BOXES**

For Steel Boxes, Motor Starting Switches, (steel enclosed), Motor Drip Pans, Motor Covers, Rheostat Boxes and Accessories.

Constructed to give the best service, and made according to the best principles of workmanship in every detail.

Illustration shows our new Service Box No. 1035, 30 Amp., 125 Volt, double pole, size 8" long x 5½" wide x 2½" deep. It has a carrying capacity up to standard and is approved by Hydro Electric Commission. By its exclusive design it can be installed in less time than any other box on the market. We install Knockouts to suit your own requirements.

Regular stock includes a complete line from 30 Amp., 125 Volt up to and including 1200 Amp., 600 Volt. We can make immediate shipments from stock of 4000 to 5000 Type E Boxes. Our object is to give service—try us.

ARMACELL *Insulating Varnish* *and* ANTI-SULPHURIC ENAMEL

An opinion by a well-known firm of manufacturing and contracting engineers:

Montreal, Feb. 25, 1919.
Messrs. SPIELMAN AGENCIES REG'D,
Montreal.

Dear Sirs,

In reply to your inquiry we have pleasure in stating that we have been using your "ARMACELL" Insulating Varnish and "ANTI-SULPHURIC" Enamel for the past ten years and they are without exception the best insulating varnish and finishing enamel that we have ever used and we use them always on our high voltage work.

Very truly yours,

FRED THOMSON CO., LIMITED,
(Signed) Per C. Thomson.

Made in London, England, by
GRIFFITHS BROS. & COMPANY

DOSSERT SOLDERLESS CONNECTORS

The Tapered Sleeve insures absolute contact.

The Principle that established solderless connectors as good engineering.

The more contact surface you get in a connection—the better the joint.

Because the tapered sleeve of the Dossert Connector gave engineers a means for securing large contact area held permanently tight—the solderless connector idea met with favor.

To-day it is standard practice.

Are you still turning down commutators on a lathe while your equipment stands idle for several hours? You can keep commutators and collector rings in smooth running order simply by using the Ideal Resurfacer while machines are under load!

One man wrote us it took him six to seven hours to have a commutator turned down on a lathe—on trying the Ideal he found he got better results in one hour and equipment was not shut down one minute.

IDEAL COMMUTATOR RESURFACER

The Ideal is an abrasive block, not a natural stone that is sometimes hard and sometimes soft, and that clogs with copper dust, but a specially manufactured product of uniform density and cutting quality throughout. By applying it as illustrated upon commutators or collector rings while in operation a smooth surface is quickly produced that saves wear and tear upon brushes and equipment.

You save time, labor and expense. Hundreds of the largest concerns in the country are constant users of the Ideal. In order that you may convince yourself of its value we will send you the Ideal on free trial for ten days. If you are not satisfied with it return it—the test will not have cost you anything.

Patent Pending U. S.

Solderless Connection

Insulating Shell and Cap

No mistake can be made with the use of Walger Connectors. There is only one Walger way and that is the right one. No Blow Torch, no acid, tape or solder, etc.—a screwdriver and a knife to strip the wire, that's all.

Passed by the National Board of Fire Underwriters and the Hydro Electric Power Commission for No. 12 wire and under.

Ask your jobber for them and Discard that Blow Torch.

Walger Connector Co.**Sales—Agent C. JACKSON, 22 College Street, TORONTO, ONT****National Board of Fire

World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a Specialist in Repairs. Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an absolutely reliable job. You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine (Profit). Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the Trade Discount (More Profit).

Others are doing it. Why not you? Write about it.

WALGER Insulated Wire CONNECTORS

**Save
Time
and
Money**

**The New
3-WAY for
Condulet
Connections
and
Tap Joints**

**Simple
Safe
Speedy
Thorough**

While you are making one connection with the old method of blow torch and solder you can make five with the "Walger," and a far better, cleaner, more satisfactory job.

A screwdriver and a knife to strip the wire are all the tools required, and there is no litter or damage to walls, ceilings or fixtures.

The "Walger" Insulated Wire Connector is approved by Underwriters' Laboratories Chicago, and Hydro-Electric Power Commission, Ontario, Canada for No. 12 wire and under. Ask your jobber for prices and discounts or write Walger Connector Co.

Patented Canada 1917.

THOMAS QUALITY PORCELAIN

Is it economy to save five or ten per cent. when buying low tension porcelain and then find you have fifteen per cent. or more rejects?

Thomas Low Tension Standard Porcelain is uniform in

*Quality
Color
Dimensions*

Every piece is inspected at the factory before shipping and the rejects are carefully eliminated. The glaze on every piece of Thomas standard porcelain is perfect and there are no "fins." These "fins" when appearing on the grooves of the insulator cut the insulation of the wires, or if on the bottom surface will cause breakage when the workman endeavors to screw them to a level surface.

Thomas porcelains may, for a small extra charge, be packed in paper cartons or in corrugated containers containing 500 pairs or pieces or 1000 pairs or pieces.

And remember, the Thomas line is complete, they make all the Standard knobs, tubes and cleats.

*Ask our nearest house to send you a Thomas catalog
and quote you prices to-day.*

NATIONAL PRODUCTS

SHERARDIZED

SHERARDUCT

The Rigid Steel Conduit with both surfaces Sherardized and Enamelled. Rust Proof and Acid Proof. Made of a high grade spellertized mild steel tubing.

Write for Bulletin 50

ECONOMY BLACK ENAMELED

ECONOMY Black Enamelled Conduit is made of the same high grade spellertized mild steel tubing as **SHERARDUCT**, the only difference being in the protective coating. In an enamelled conduit there's none better.

Write for Bulletin 50

FLEXTUBE

Interwoven — Seamless — Non-Collapsible. Inseparable and Double Compounded. Easy to fish and every foot of every coil can be used

Write for Bulletin 151

FLEXTUBE

We cannot tell you *all* about *all* National Products in this limited space, but we want to call your especial attention to certain features of **FLEXTUBE** Double compounded, Non-Metallic Flexible Conduit.

It's the original seamless interwoven non-collapsible, non-metallic flexible conduit with the "roller-bearing" interior. There's absolutely no waste; every foot of every coil can be used, and it's so easy to fish that it's a pleasure for the wiremen to use it. That makes it profitable for the contractor, and its quality is such that the best interests of the owner are served. Note the construction. The seamless interwoven tubing compounded; then the protecting outer braid, also compounded—a double compounded tubing which is satisfying to those who insist upon the highest quality. Place your order for your requirements with your jobber; specify by name—**FLEXTUBE**.

When You Sell

LACO LAMPS

You stand up and square your shoulders with fullest assurance—With Laco Lamps you are sure of your ground. You know that a lamp that gives equal light (by the most severe laboratory tests) with all other lamps, but also is so sure of its ground that it gives an individual guarantee for 1500 hours against all other average guarantees of 1000 hours (and who is to determine the “average?”) **MUST** be “some lamp.”

Every advantage is yours when you handle Laco.

The profit is rightly based—Larger sales efforts bring larger profits. Dealer profit is assured on all sales, and a fixed retail price is steadfastly maintained.

The Laco Dealer need not carry heavy stocks, as there is available at all times a quick distribution of goods from Laco Warehouses, and from Jobbers in all parts of Canada.

Laco Lamps are your opportunity.
Write us to day for particulars.

Canadian Laco-Philips Company, Limited

Toronto

Winnipeg

Vancouver

"I have specified Edison Mazda Tungsten Lamps

Because I know them to be the most reliable lamp on the market. Their service is the longest, their use of current the most economical, and they never vary in their brilliance."

Mr. Dealer

This is the reputation of Edison Mazda Lamps on which you can build profitable and satisfactory sales. It means honest value, by reason of high grade workmanship and materials and the subjection of every lamp to the proper test before it leaves the factory.

The Edison Mazda is a Canadian-made Lamp—the product of Canadian Capital and labor.

Our literature will help you and we shall be pleased to co-operate with you in getting the maximum lamp sales from your district—Write us now.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance.
Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is \$66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

Universal Insulator Supports

SAVE

Time, Labor and Material

UNIVERSAL INSULATOR SUPPORTS are specially designed malleable iron clamps made in four sizes for securing insulators to open steel framework for wiring mills, foundries, shops, bridges, piers, elevated railways, subways, train sheds—and similar structures. They are easily attached, and by their use, electric wiring for lights, motors, generators, cranes, etc., can be installed with a great saving of labor and material.

*Sand, Gravel, Coal, etc., Easily
Loaded with a Scoop Conveyor*

**Does the work of from
6 to 12 men**

in loading coal, coke, ashes, sand, gravel, dirt, crushed stone, etc., into trucks or cars or transferring it from one place to another.

Used in connection with handling coal or ashes around the power plant or for digging ditches or building roads, it is one of the greatest labor and time savers. It keeps equipment moving. Enables men to work faster and easier. Eliminates much shovel and wheelbarrow work. Does three to five days' work in one.

OVER 1000 USERS

The Scoop Conveyor has been adopted by over 1,000 leading contractors, manufacturers and coal dealers because it is durable, light, compact, easily moved around and low in cost. About one-half of our sales are "repeat orders."

It is called "Scoop Conveyor" because the carrying belt receives its load over a scoop which can be pushed or completely buried into the material to be conveyed. This permits of scraping the material onto the carrying belt instead of lifting it by shovelfuls into the receiving hoppers fitted to ordinary portable belt conveyors and results in a saving of fifty per cent. of the labor in feeding.

Dependability

There are three distinct features about C.G.E. Electrical Appliances which should be borne in mind by the Dealer when selling Electrical Labor-Saving Devices to the housewife, namely:—Reliability, reasonableness in price and simplicity.

Undoubtedly the most important is reliability. Sell the housewife an appliance that "won't work" without having to be coaxed and tinkered with and you stand a very slim chance of ever persuading her to buy anything else electrical.

But once gain her confidence by selling her something that will work every day of the week without fail, and you have made a friend as well as a customer who will boost your store better than paid advertising.

C.G.E. ELECTRICAL LABOR-SAVING DEVICES GIVE ONE HUNDRED PER CENT SATISFACTION ALL THE TIME.

Reasons for R & M Fan Reliability

Reason Five — The Gear Mechanism

The steel worm and bronze gears of the R. & M. Oscillating mechanism are accurately fitted and carefully adjusted in assembling. They produce a smooth, even oscillation and the power consumed by the oscillating mechanism is practically negligible.

The gears are mounted in a grease-tight box which is packed with hard oil, insuring thorough lubrication and long life for the parts. A felt-packed, screw-type stuffing box prevents any leakage of grease around the oscillating disc shaft.

Devoe Type "A" Externally Operated Safety Service Switches

MADE IN CANADA

BY CANADIANS

FOR CANADIANS

- | | | |
|---|---|---|
| (1) Steel box built according to the latest rules of the Hydro. | (7) Square steel operating rod having moving arms attached and connecting to yoke enabling all blades to make contact at same time. | (11) Locking device to prevent switch being closed if necessary. |
| (2) Slotted screw hole enabling one man to install same (This is of great help to the wireman). | (8) Snap catch with hole for padlock. | (12) Strong check preventing strain on switch when operating. |
| (3) Front Jaws make 90% contact. | (9) Monson Slate Base. | (13) Blades are made of 98% Pure Copper having two spring washers well rivetted to hinge jaws and making 90% contact. |
| (4) Auxiliary quick break blades attached direct to blades. | (10) Holding-down screws enter from back with nuts on top, making removal of switch easy. | (14) Fibre yoke mounted on copper blocks pinned and soldered to blades. |
| (5) Extra heavy Cast Iron Handle. | | |
| (6) Moving arms made of iron well rivetted together and connect- | | |

STUDY POINTS No. 6, 7, and 13

No. 6 The moving arms, as shown, are constructed in such a way as to give positive and uniform motion to the switch blades; thereby making all three (3) blades enter their contacts at the same time. With this construction, there is no danger of a three phase motor running single phase, or starting fuses being blown.

No. 7—The square rod used on our switches is turned round at each end, to enter bearings fastened to sides or box. This rod only acts as an axle, turning to move the arms No. 6, and not directly as an operating crank and handle combined, as in other switches. It is not subjected to strain or twisting, which distorts contacts and blades of switch in operating.

No. 13—The construction of our switches enables us to get 90-95 per cent. contact at hinge and front joints. We know of no other make of externally operated switches that gives this amount of contact. A close study of our switch, as compared with other makes, will convince you of DEVOE QUALITY.

All our Safety Type Switches are examined and labelled under direction of the HYDRO-ELECTRIC POWER COMMISSION OF ONTARIO.

Electrical Engineers to Form Canadian Institute

There is more than usual interest attaching, at the moment, to the question of whether the electrical engineers in Canada shall form themselves into a Canadian Institute of Electrical Engineers or whether they shall merge their identity in the organization which, until recently, has been known as the Canadian Society of Civil Engineers and is now called the Engineering Institute of Canada. The new name would indicate the intention that all branches of engineering should be included in one large and more comprehensive organization, but beyond the change in name there is little evidence that the personnel of the Engineering Institute of Canada is different from that of the Canadian Society of Civil Engineers. This view is borne out by the fact that neither the Society of Mechanical Engineers, the Society for Chemical Industry, the Canadian Mining Institute, Canadian branches of the American Institute of Electrical Engineers nor the Municipal Association of Electrical Engineers have looked upon the proposition of becoming part of the Engineering Institute of Canada with favor.

So far as electrical engineers are concerned, it is apparently the practically unanimous opinion that their first interest, and duty, lies in doing all in their power to develop the industry of which they form a part. It is true there are certain things in common between electrical engineers and

other engineers but the relationship is not nearly so close as that between electrical engineers and electrical manufacturers, jobbers, central station men, contractors and dealers. The development of electrical engineering as a profession is tied up hand and foot with the development of these other sections. No one element in the industry can prosper, or even exist, without the others. All these elements are members of the same family—a young one, truly, but growing very rapidly—to which every member must contribute his quota.

What we electrical men need—and we need it very badly—is some scheme of organization which will bring our various elements into close working relationship. We are as yet, so to speak, merely held together by sentimental ties of common interest. Cold business demands, however, that the electrical industry, as a whole should be organized under one general head—it may be an individual or a group of individuals—which shall look upon the whole industry as a unit and administer the various departments impartially, having nothing in view but the highest development of the whole—just as the manager of any private industrial concern co-relates his various departments to the end that the business over which he has been placed may be increasingly prosperous. The easiest way to accomplish this end would seem to be through a common council, containing representatives from all the sections of the industry. This, however, presupposes some corporate body to elect these representatives. There is such a body of electrical manufacturers, of jobbers, of central stations and of contract-dealers. There is none of electrical engineers. Isn't the first logical step the formation of such a body whether you call it the Canadian Institute of Electrical Engineers or any other name?

Large Number of Telephone Conversations on Same Circuit

A few days ago the Canadian Independent Telephone Company staged a most interesting experiment over the Toronto-Dundas telephone line of the Ontario Hydro-electric Power Commission. Due to the operating conditions in this district the ordinary metallic system has become very indistinct and frequently is quite useless, so much so that the Commission is considering the advisability of installing another line.

The experiment was in charge of Dr. Lee de Forest, with Professor Charles A. Culver and his staff of experienced operators, and it was demonstrated not only that the equipment used rendered conversation on this line distinctly audible but that the capacity of the line was already sufficient to carry on a large number of simultaneous conversations. The basis of the success of the test lies in the recent invention of the De Forest "Audion"—an instrument for the production of high frequency waves. A brief resume of the situation will be of interest:

General George O. Squier, Chief Signal Officer of the U. S. army demonstrated at Washington, in 1911, the possibility of transmitting high frequency carrier waves similar to those used in radio telephony over an existing wire telephone circuit. He was able to demonstrate by this means the possibility of carrying on several simultaneous telephone communications without interference and without disturbing the conversation over the physical circuit. General Squier used in this early test a special high frequency alternator which was very expensive to build and required constant attention of a skilled engineer. Moreover, the frequency delivered depended exactly on the speed, and this was a variable quantity which was very difficult to regulate quickly or to keep constant when once set.

This fact necessarily confined the application of the idea to laboratory demonstrations. It was not until the de

Forest Audion (originally developed as a radio detector and later applied as a telephone amplifier or repeater on the long distance lines of the A. T. & T. Co. in the United States) had demonstrated its ability to act as a high frequency generator of waves of absolutely constant frequency—that it was possible to hope to apply the principles of the “wired wireless” multiplex telephone in practice.

The oscillating Audion thus used was called by its inventor, Dr. Lee de Forest, the Oscillion. The Oscillion in various sizes and built for powers ranging from a fraction of a watt up to 1,000 watts or more has enjoyed an enormous application to all problems of wireless communication during the war. Literally thousands of these little high frequency generators have been used by the U. S., British and French Signal Forces, and it is a well known fact that very much of the success which attended the artillery and aviation operations of the Allies can be laid to the door of this little lamp.

As soon as the war was over the telephone engineers began to apply the Oscillion to the question of multiplex telephony according to the Squier inventions. Engineers of the de Forest Company have been pioneers in this application and Toronto has just witnessed an application by these engineers of the oscillating Audion to multiplex telephony.

The demonstration was carried on over a pair of telephone wires belonging to the Hydro-electric Commission extending from the power station at Toronto to that at Dundas near Hamilton, a distance of over 40 miles. The apparatus was arranged at the power stations instead of at the downtown terminals because better facilities for carrying on the experiments were there offered. Tests were made, however, over the three miles of cable extending from the power station at Toronto to the central office of the Hydro-electrical Commission. These tests showed that the presence of the three miles of cable caused no appreciable attenuation to the service, a result which may come as a shock to some of our mathematical telephone experts.

Two complete transmitters and receivers were installed at each end of the line. Four distinct wave lengths or frequencies were employed ranging from 16,000 to 12,000 meters. Additional tests were made using wave lengths of 600, 1,000 and 1,600 meters. Contrary to all expectations, the results obtained with the higher frequencies, (the highest being 500,000 per second), were even better than those one-twentieth as great. The demonstration showed by actual trial that at least seven simultaneous conversations could be carried on without interference of one with any other, and without in any way disturbing the physical circuit. The existing conditions of the line were not disturbed in any way except momentary interruption while choking coils were being introduced. It was found later that these choking coils were not necessary.

The quality and loudness of the speech left nothing to be desired. Hundreds of conversations were carried on during the time that the apparatus was in use, by visitors who had never seen the apparatus before and knew nothing at all about its manipulation. No difficulty whatever was experienced by these visitors. Simultaneous talking and listening was carried on the same as over an ordinary telephone circuit, no switch-over device being employed to switch from talking to listening. The operation of the system was shown to many leading engineers of Toronto and Hamilton, including representatives of the Hydro-electric Commission.

The success of the demonstration using these extraordinarily high frequencies so utterly new to the wired telephone art, upsets a good many of our preconceived and orthodox notions of the limitations of telephone operation and engineering. Thus it is clear that with no more than two pairs of telephone wires, 60 independent telephone conversations can

be carried on without using the ground, and with ground connections six additional circuits can be provided which should be suitable for telegraph purposes. Over each of these latter circuits it would be possible to carry on ten additional telegraph communications suitable for high-speed work. It has been demonstrated that copper wires are not necessary for this form of telephone communication; galvanized iron wires such as are used for ordinary telegraph circuits, answering admirably. There is no question but that most power transmission conductors can be very nicely used for telephone purposes as well.

The results of the widespread extension of telephone and telegraph communication which this new Squier-de Forest invention permits are difficult at this early date to limit or define. The ease with which the wired and wireless telephone systems can be dove-tailed together (so that the permutations possible by an ordinary switchboard can be utilized to interconnect the two systems) assures a very great extension of telephone service throughout the province and throughout Canada. The application of “wired wireless” should also greatly reduce the cost of service, especially for long distance trunk line work. We may now expect that a long distance trunking service will soon be linking up many independent or isolated telephone exchanges, which for many years to come, could scarcely hope to afford the old style long distance communication.

The Metric System—Discussion at a Joint Meeting of the A. I. E. E. and the A. S. M. E. (Toronto Branches) at Engineers' Club Friday May 11, 1919

By Mr. E. V. Pannell*

E. F. Burton (Professor of Physics, Toronto University) introduced the subject by a contribution to the origin of the Metric System. The derivation of the meter was due to the action of the French Government in 1793 and in surveying the length of the meridian from Dunquerque to Barcelona it was believed that this value was $1/10$ deg. part of the earth's quadrant. The fact that this was found to be slightly in error at a later date did not greatly disturb the value of the system because if all the standard meters were destroyed the value could always be reproduced by a definite wave length of cadmium red light. The decimal system was older than civilization, being derived from the number of digits with which primitive man was in the habit of counting; the metric system carried this step further. One great advantage was the facility of relating weights and measures from the intrinsic relation holding in this system. The volume of a tank of water or oil was its weight and vice versa.

E. V. Pannell (engineer, British Aluminium Co. Ltd.) pointed out that arguments for the English system of weights and measures were not directed against the decimalization or other improvement of the system where it was found desirable. As a matter of fact, the inch had been excellently decimalized in connection with wire sizes and sheet gauges which were always specified by the mil. Nevertheless, the system of successive halving leading to the $\frac{1}{4}$, $\frac{1}{8}$, etc. fractions was in many respects a more natural method and would always hold in certain connections. Since the meter had been proved to be no particular fundamental measure but only an arbitrary one like the yard why not standardize the yard which was about a thousand years older. The Metric System was adopted by the French Government in a time of revolution which also included a ten day week, a new system of months and a 400 degree circle. On the other hand, the older units evolved naturally; the

*Secretary Toronto Branch A.I.E.E.

yard being the maximum convenient width of cloth which could be woven and the inch a definite measure of the number of threads also corresponding to the length of the weaver's thumb. The yard is common all over Spain and Latin America and even in Texas as the Vara. The lack of relation between units often urged against the English system was not found any objection in practice. Certainly one litre of water at maximum density and 4 deg. C weighs a kilogram but under the same circumstances a cubic foot of water weighs 62.3 lbs. as every schoolboy knows. The metric advocate might know how many square mm there are in a hectare, but how much better off is he for knowing it. One might as well ask how many circular mils there are in an acre. Both are measures of area but for practical work there is no need for any close relation between them. Regarding foreign trade, letters had been received in answer to a canvass by the A. S. M. E. on this subject and showed that 82 per cent. of the manufacturers had found not the slightest need for the metric system in machinery and other products for foreign markets and only 11 per cent. had found it occasionally necessary.

W. P. Dobson (Laboratory Engineer, Hydro-electric Power Commission) thought that some of the objections against the adoption of the metric system were based upon an immediate change. Necessarily it would have to be gradual and preceded by a period of education. He outlined the excellent system by which the units of the system were inter-related and defined the fundamental units. It is intrinsically a decimal system and the universal tendency towards the decimal fractions gave this the only perfect decimal system a great advantage. The matter of coinage was a great argument in favor of division by ten. This simplicity of the system involved a reduction in the time of school estimated at from 1 to 3 years. The fact which tells most against the older systems is that there are several forms of each unit; different values for the pound, gallon, etc., also the various wet and dry measures, etc. The great advance made by the metric system in only 100 years was evidence of its value. It had been so widely adopted that the nations still working on the English system were in the minority. The metric measure was obligatory in 34 countries and legal in 26. Many firms making machinery, tools, etc., in U. S. regularly manufacture and list goods in metric measurement side by side with the English system. Such important firms as the Baldwin Locomotive Works, Brown and Sharpe Mfg. Co. and American Locomotive Works are among these. Outside the field of manufacture the Wholesale Grocers' Association had brought in a resolution in favor of the change of system.

C. G. Spencer (American Society of Mechanical Engineers) had come into considerable contact with the metric system in Latin America and was surprised to find how much the English system was still used in engineering work. He found that the difficulty about the correct location of the decimal point was not exaggerated and a great number of mistakes was due to this course. The use of feet and inches provided a safeguard against this because the units are so different.

E. T. J. Brandon (Engineer, Hydro-electric Power Commission) was convinced of the advantage of a decimal system of coinage from recent experiences in England and Sweden where he found it much easier to calculate currency in the latter country. He thought that the objection mentioned by Mr. Pannell to the great variety of pipe fittings required during a transition period could be simplified by the adoption of a metric-English union.

W. F. McKnight (Northern Electric Company Ltd.) believed that a standard system was greatly needed on con-

nection with the size of wires and cables. There were at least ten different wire gauges in common use.

H. W. Price (Professor, School of Practical Science, University of Toronto); Perry A. Borden (Meter Engineer, Hydro-electric Power Commission) and W. F. Sutherland (Editor, Canadian Machinery) also contributed to the discussion.

Another Unit for Saguenay Company

The Saguenay Light & Power Co. are carrying out the reconstruction of their plant at Ha! Ha! Bay, P. Q., and will install an additional unit. It is proposed to exchange the Chicoutimi Pulp Company's common shares for a like amount, par value, of common shares of the Saguenay Power Company; to increase the number of preferred shares from 25,000 to 30,000, and to reduce the dividend thereon from 7 per cent. to 6 per cent. cumulative from April 1st, 1919; to change the preferred shares into Saguenay Power shares, and to increase the number of directors of the Chicoutimi Pulp Company to nine. The Saguenay Power Company will become the Saguenay Pulp and Power Company, and proposes to acquire the controlling interest in the Chicoutimi Pulp Co., the St. Lawrence Pulp & Lumber Corp., the Chicoutimi Freehold Estates, Ltd., the Roberval-Saguenay Railway Co., the Saguenay Light & Power Co., and the Chicoutimi Port Co.

Water Powers Must Be Developed

Sir Lomer Gouin, in a statement announcing a dissolution of the Quebec Parliament, outlines a policy in regard to the waterways. "These", he says, "must be developed, which means the dotting of this province with manufacturing centres such as Three Rivers, Grand'Mere, Shawinigan, Chicoutimi, Sherbrooke, Drummondville and other centres. Cheap power means more manufacturing and more business, more work, more employment, more money, more labor, more consumption of foodstuffs, more work for the farmer, all of which means better living conditions and general prosperity for all classes of the community. To carry out all this, money must be expended. It may be necessary to borrow, but now is the time for investment."

Itinerary of Royal Naval Exhibition

The Royal Naval Exhibition, comprising a wonderful display of photographs showing the activities of the navy in the war, is being shown at a number of centres throughout the Dominion. In Toronto and Hamilton, where this remarkable set of pictures has been displayed, the keenest interest has been shown. The following dates have been definitely determined: London, May 19 to 26; Windsor, June 2 to 7; Port Arthur, June 23 to 28; Winnipeg, July 7 to 12; Regina, July 21 to 26.

Calgary, Vancouver, Victoria, Edmonton, Saskatoon, Sherbrooke, Quebec, St. John and Halifax will also have an opportunity of seeing this display at dates not yet fixed. The exhibition is under the auspices of the Navy League of Canada.

Mr. Pannell Going to New York

Anticipating the departure in the near future of Mr. E. V. Pannell, of the British Aluminium Company, who is leaving Toronto to open a New York office for his company, the local members of the A. I. E. E. at their last meeting presented him with a travelling bag. Mr. Pannell has very acceptably filled the office of secretary of the A. I. E. E. for the last two years and it is with great regret that his many friends have heard that the expansion of his company's business necessitates his removal across the line.

Steam-Electric Plant of the Dominion Power and Transmission Company, Hamilton

II.—The Turbines and Auxiliary Steam Equipment

The Turbines

Steam at 200 lbs. pressure and 160 deg. superheat is admitted to the turbines, by piping hidden from view in the turbine room. A surface condenser is situated immediately below each turbine. The condensate and air from the condenser is handled by an air and condensate pump coupled on a common shaft, and driven by an impulse turbine.

The turbines are Westinghouse type, multiple expansion, parallel flow design, known as "Impulse Re-action" type. The impulse section consists of two rows of moving and one row of stationary blades; the balance of the machine consists of blading of the re-action type. The impulse blades are of nickel iron and the re-action blades of phosphor bronze. Main bearings are self-aligning. Lubrication is oil pump operated from worm gear on the turbine shaft, with delivery and return piping from and to receiving reservoir and bearings, with sufficient head to insure ample flooding of bearings.

Speed variation at normal conditions can be controlled within 3 per cent. to 4 per cent. if desired. Speed-changing device for remote control. Primary admission valves of balanced Poppet type are enclosed in steam chest. The secondary valves are automatically operated by mechanical connection with the governor, and arranged to admit steam to additional stage when load exceeds capacity of turbine when receiving steam through primary valve. The valves will similarly operate should vacuum or steam pressure fall to point where the turbine is unable to normally carry load, and return to seat when excess capacity is no longer required.

A quick-operating throttle valve operates from separate safety governor, to automatically close valve before turbine speed exceeds safe limit. This is capable of adjustment for predetermined speed. Means are provided for tripping by hand in close proximity to turbine.

Operating under conditions of 200 lbs. gauge pressure at throttle, 160 deg. superheat at throttle, 28½ in. vacuum in

exhaust pipe referred to atmospheric pressure of 30 in. and at speed of 2,000 r. p. m. the maximum capacity of turbine is 11,000 kilowatts.

Piping, Etc.

The superheater steam lines carry 200 lbs. working pressure, 180 deg. superheat; saturated steam lines, 200 lbs. working pressure. All straight pipe and bends are 2½ in. and larger, of full weight open hearth soft steel; flanging and bending pipes, sizes 2 in. and under, are of same material but extra heavy pipe.

The 2½ in. flanges are extra heavy rolled steel, welded to pipe by the Kellogg forge welding system, in which the flange is first shrunk on the pipe to prevent oxides from forming, then heated in oil furnace to welding temperature and welded with steam hammer, the weld being made solid from face to back of flange.

All outlets on steam lines are extra heavy open hearth forged steel, with flanges welded on by above method. Outlets were welded to mains by Kellogg electric welding process on which fillet is built up 2½ times the thickness of the original metal, weld being hammered during welding to insure close grained metal and then annealed to remove strains caused by high welding temperature. Special 14 in. x 7 in. manifold fittings are made by swedging, a tapered reducer being used at either end, the 7 in. outlets being forge welded to the 14 in. body.

Fittings are of extra heavy cast steel flanged, on sizes 2½ in. or larger; extra heavy cast steel screwed on sizes 2 in. and under.

Valves have cast steel bodies and caps, rolled Monel metal spindles and Monel metal discs and seats. Gate valves are Chapman. Non-return valves are Foster. Small globe valves for throttle valves Jenkins.

Drip and drain pipe is installed from all high and low pressure piping. In high pressure drips, extra heavy cast

Close-up view of one of the 12,500 kv.a. turbo-generator units of Dominion Power and Transmission Co.

steel piping, extra heavy cast iron fittings and extra heavy brass globe valves are used. There are two crane Tilt traps, one for each unit. The low pressure drip and drain piping is made of standard weight material throughout.

Exhaust Steam Lines

Piping is standard lap welded steel throughout except 36 in. atmospheric exhaust from atmospheric relief valve, which is 5/16 in. thick lap welded and supplied with copper flashing at roof line. Piping between atmospheric relief valve and condenser of cast iron. Flanges are standard cast iron, screwed and refaced, except 36 in. pipe, where steel flanges and vanstone joints are used. Fittings are standard cast iron flanged. Inlets to 36 in. exhaust risers are of forged steel, welded on. Expansion joints are corrugated copper bellows type.

36 in. atmospheric relief and back pressure valves are Atwood and Norrill standard make. Twin exhaust valves at heaters have their stems geared together with intermediate wheel, so that one valve is open when the other is closed. An 8 in. constant pressure valve with safety closing device, operated from the turbine auto-governor, is connected between excess steam outlet from each feed water heater and main turbine. These valves were made by the Westinghouse Machine Company.

Waste steam from the safety valves is piped to atmospheric exhaust.

Boiler Feed Lines

The piping is extra heavy lap welded steel galvanized. The flanges are the same as for high pressure piping—galvanized. Outlets are welded as for high pressure steam piping. Fittings of heavy cast steel flanged same as for high pressure steam piping. Elbows have long radius where possible. Gate valves are Chapman with hard bronze spindles, discs and seats, steel bodies and caps, outside screw and yoke. There are two 6 in. Crane extra heavy flanged cast steel body swing check valves, one at each feed pump.

Low Pressure Water Lines to Heater and Feed Pump

Piping is standard weight cast iron tested to 300 lbs. high pressure, pipe bends being used in place of elbows where possible, to keep joints down to minimum. Valves are standard weight cast iron, bronze spindles, discs and seats, outside screw and yoke.

Feed Make-up Lines

Piping is standard weight lap welded steel, galvanized. Flanges are standard cast iron, screwed and refaced. Fittings are standard weight cast iron flanged. Valves are standard weight cast iron, bronze spindles, discs and seats, outside screw and yoke.

Blow Off Lines

These connect to sewer. Piping is extra heavy steel, lap welded. Outlets are welded as for high pressure steam. Flanges and fittings—as for high pressure steam.

Condenser Piping

Piping is standard weight cast iron. Valves are Chapman 10 in. and 26 in. list 58½, and 8 in. list 24, solid bronze spindles, seats and discs, outside screw and yoke.

Surface Condensers

Condensers are two-pass surface type 1, water inlet at bottom and water outlet at top; steam to enter top of condenser. Tube plates are Muntz metal, 1¼ in. thick. 3,040 tubes, 1 in. outside diam, No. 20 gauge (Birmingham) and 18 ft. 10 in. active length of Muntz metal have effective cooling surface (measured on outside of tubes) of 15,000 sq. ft.

13,800 gallons of water per minute will maintain the fol-

lowing vacuum referred to a 30 in. barometer when handling the amount of steam mentioned below:

Temperature of injection water in deg. F. 68;

Condensed steam lbs, per hour, 143,000;

Vacuum, 28.

Pumps

The air pump is of the Westinghouse-Leblanc rotary type with runner of solid bronze, size No. 20 and capacity 12-2/10 cubic ft. per second. The condensate pump is centrifugal type; conditions of operation are: discharge head external to condenser not exceeding 25 ft.; speed, 2,500 r. p. m. The air and condensate pumps are mounted on common

General view of Turbo-generators during erection.

shaft and driven by a Westinghouse impulse turbine. These turbine drives are designed to carry full load with 150 lbs. steam pressure, 100 deg. superheat and zero back pressure.

Cooling Water

The cooling water for the condensers is pumped from Burlington Bay by circulating pumps situated below the surface so as to be self-priming.

The circulating pump runners are of closed impeller type. Conditions of operation are as follows: friction head in pipe 2 ft.; level of intake below discharge water, 1 ft.; total pumping head, exclusive of friction head through condenser, 2 ft. The circulating pump is driven by a Westinghouse impulse turbine through Westinghouse reduction gear. This gear is Westinghouse self-aligning type, double helical gears, one right and one left hand, to equalize end thrust. The large gears are carried on solid bearings.

Exhaust steam from the turbines driving the auxiliaries is admitted to Cochrane open type feed water heaters for heating the boiler feed. The feed pumps are each large enough for feeding the boilers under maximum conditions. Figure 3 shows in part air and condensate pump—heater, fan engine and boiler feed pump.

Boiler Feed Pump and Turbine

The turbines are Westinghouse horizontal impulse type with following operating conditions: Pounds steam at throttle, 200 lb. and may drop as low as 150 lb. at times; back pressure 0 lbs. non-condensing; superheat at throttle 160 deg. F.; r. p. m., 2,500. Operating under these conditions the

capacity is 125 B. h. p. The admission valve is balanced Poppet type and is operated by mechanical connection with governor. Variation at normal load is 3 per cent. which may be increased if required. The pump is Westinghouse multi-stage centrifugal, horizontal volute type, double suction. The impeller is of bronze.

Operating conditions:—Capacity U. S. gallons per min., 525; number of stages, 3; maximum temperature of water, 210

General view of turbo-generator room.

deg. F.; total head including friction, 520 ft.; r. p. m., 2500; diameter in suction, 8 in.; diameter of discharge, 6 in.; h. p., 125; steam pressure, 200 lb.; vacuum atmospheric exhaust; The approximate weight of pump is 4,100 lb.; weight of prime mover, 1,800 lb.; total weight, 5,900 lb.

Lighting for Production

Mr. W. A. Durgin recently gave an interesting address before the Illuminating Engineering Society, entitled "Lighting for Production." By means of a factory model showing cross section of a typical machine shop and a translucent working plane, the effects of modification of several factors in daylighting were demonstrated in comparison with the results obtained from the usual local lighting systems in practice. The intensity, shadow production, and uniformity of the lighting was considered, the treatment leading up to the superior results obtained from a general lighting system giving productive intensities. The value of this type of installation was shown by the detailed data obtained from four careful tests in industrial plants where the actual production under the high intensity could be compared with that when the old low intensity systems were used. Examples of several recent units in the 300-watt size were exhibited, and emphasis placed on the special adaptation of each to certain classes of installation.

Hamilton Electrical Association

The Hamilton District Electrical Association, which is composed chiefly of electrical contractor-dealers has decided to operate, in future, on the Open Price Plan. Mr. V. K. Stalford, president of the association, has very kindly consented to act temporarily as secretary of this scheme, so that it may be got under way at once.

Storage Heaters for Electric House Heating

By Mr. H. B. Dwight

The fact that house-heating loads of 3,000 kw. and 5,000 kw. have been built up in electric power systems in irrigation districts, where the winter heating load is an off-peak load to the larger irrigation load of the summer, suggests the question whether off-peak energy could not be used economically in other water power systems.

Since in most power systems the peak load occurs daily for two or three hours in the late afternoon, a heating system using only off-peak energy would have to make use of stored heat during those hours. This might be accomplished by utilizing storage heaters connected to a separate supply circuit which could be opened by the substation operators from approximately 3 p.m. to 6 p.m. During that time the storage heaters would automatically open up and deliver their stored heat, so that the lack of the electric power would not be felt. Such a heating load would be an off-peak load provided that it were smaller than the total regular load, which would be the case since electric heating would be used only in the more favorable cases.

If reliable automatic storage heaters were available, factories with a variable motor load could use the off-peak energy of their motor load for heating purposes. This off-peak energy is sold in various localities served by water power at an extremely low rate per kw. hour. A relay could be set to open the heating circuit whenever the motor load increased beyond a certain point, and to close the heating circuit when the motor load fell again. Rooms and buildings could in this way be heated with exact automatic control, without increasing the maximum demand of the electric power load of the factory. A relay could also be used in this way in a substation, so as to give only off-peak energy to the heating circuits.

It might be thought, at first sight, that storage heaters would be undesirable from the householders' point of view, but the opposite ought to be the case, for storage heaters can provide an element of permanence and reliability not obtainable with usual electric heating devices. With an automatic storage heater in every room, designed to maintain the temperature practically constant by stored heat for a three-hour peak period, if power should go off accidentally for three hours the fact would scarcely be noticed. With non-storage electric heaters, however, the room temperature would fall an uncomfortable number of degrees in case of the failure of power for one or two hours. Cases where the failure lasts longer than three hours are very rare with modern systems. The storage heaters would be just as advantageous in cases of breakdown of any part of the apparatus in the house. The trouble could be repaired in two or three hours, and in the meantime the storage heaters could be opened by hand to make their supply of heat available, in case they failed to open automatically.

The difficulty of developing a storage heater which would open up automatically in order to deliver up its stored heat when required, and which would hold the room temperature constant within a very few degrees over a considerable period of time, would not seem to be an insurmountable obstacle.

In the first place, the amount of storage material required is not excessive. Assume that one watt per cubic ft. of the room to be heated will keep the temperature at 70 deg. F. in cold weather. If the room has 2,000 cubic ft. and if the "power-off" period is 3 hours, then 6,000 watt-hours, or 20,500 British thermal units, will be required to be given off by the stor-

age material. The first visible redness in a hot body occurs at 980 deg. F., a regular dull red heat being about 1,290 deg. F. If it is assumed that the storage material cools from 800 deg. F. to 200 deg. F. in the three hours, the fall in temperature will be 600 deg. F. Since the specific heat of concrete is about 0.25, that of water being 1, it is seen that 120 lbs of concrete would be required as storage material. This would mean, for example, two plates 1.5 inches thick, 12 inches high and 40 inches long. If iron were used instead of concrete, the specific heat would be about 0.12. There would be required two iron plates 1 inch by 12 inches by 40 inches. It would be quite economical and appropriate to use much heavier storage plates than these, for the purpose of giving out heat during the peak load period, so that the price for electric energy could be lowered.

In order to indicate a possible method of developing a storage heater, the following arrangement is suggested. Mount two storage plates similar to those described in the preceding paragraph, with the necessary heating elements between them. Enclose the plates in a heat-insulating case, large enough to leave air-space around the plates. The case in turn might be surrounded by a ventilated metal cover. See Fig. 1.

Provide one small door in the top and one in the bottom of the heat insulating case, and arrange these so that their natural position is open, due either to their own weight or to counterweights. These small doors may be held shut by an electric solenoid whenever the voltage is on.

In regular running, an electric thermostat placed at some suitable part of the room will turn the current on or off from the heating elements as required to keep the temperature of the room at the desired figures. The operation of such thermostats is not in doubt, since they have been considerably used in practical operation with electric heating. Heat will escape slowly through the insulating case in sufficient quantity to keep the room warm. The storage plates will become and will remain hot.

When the voltage goes off at the commencement of the peak load period, the solenoid will be de-energized and will allow the two small doors to open. Air will then flow through the doors and past the hot storage plates and so heat will be given to the room even faster at first than when the current was on and the doors in the case were closed. The room temperature may rise slightly, but will fall in time as the plates become cooler. The return of voltage will energize the solenoid and shut the doors, and the heating elements will commence again to deliver heat.

The temperature attained by the storage plates would depend on the weather, and would be in proportion to the work they would be required to do. On very cold days, the electric thermostat would be providing a large amount of current continuously while power was on. The plates would become very hot and when power went off a large amount of heat would be in storage, which would be required, on account of the cold weather. In milder weather, the plates would not attain such a high temperature in steady operation, and the stored heat would be less. This would lessen the tendency of the storage plates to overheat the room in mild weather when the power was off.

In spite of the above consideration, however, it is probable that further refinements would be necessary in order to keep the room temperature constant within a few degrees for two or three hours. Additional larger doors could be provided in the insulating case, resting by overlapping edges against the small doors previously described, and held shut by latches. When the small doors were shut by the solenoid, the larger ones would be carried shut and latched shut. Then, when power was off, if the small doors were not sufficient to keep the room warm, a special thermostat would trip the latches

of the larger doors, thus sending heat into the room at an increased rate.

It would be possible to use latches on the smaller doors, so that the solenoid would be required to operate only momentarily. The solenoid would therefore be of smaller size, and would not give out any hum during regular operation, since it would be energized only at the moment of closing the doors. It would also be possible to arrange the control so that if the room had become cool while voltage was off, the

Fig. 1—Section of Storage Heater

doors would not close and the heating elements would supply heat direct to the room until the temperature rose to the standard value.

If such a heater were installed in every room of a house, the temperature of each room would be constant irrespective of wind or weather. This would seem to be an ideal arrangement from every point of view. It would overcome the most common defect of all heating systems, namely that when the wind changes its direction, certain rooms become difficult to heat. This arrangement would also eliminate the discomfort and the cost due to overheating. No attention whatever would be required, except in cases of unusual conditions or of failure of the apparatus. In such cases the electric circuits and the doors in the heat insulating case could be opened and closed by hand.

For instance, for sleeping apartments the power circuit could be opened at night and the doors in the heater case could be fastened shut. The stored heat would therefore come out very slowly indeed, which would be a desirable feature. In the morning the doors in the case could be fastened open and the power turned on to give direct heating. For living rooms, it is probable that no adjustments would be made at any time, as a constant temperature would be the most desirable condition.

It is evident that a storage heater should be very substantially and reliably constructed. It should be designed so as to withstand continuously the highest voltage given by the circuit, without fire hazard, even if the thermostat failed to cut off the current.

It may be noted that off-peak energy has the lowest cost with water-power systems which do not have water storage. Off-peak energy has a higher cost with steam stations, and so where steam power is used, electric heating is not likely to be economical. However, in the more favorable districts this application of electric energy may be worth developing.

A New Type of Electric Furnace

By Axel Sahlin*

The electric furnaces hitherto constructed may be divided into three different groups, viz.

- (a) Induction furnaces;
- (b) Furnaces with a free-burning arc; and
- (c) Furnaces relying on a direct arc between the metal and the bath.

The first-mentioned type of furnace is now only occasionally found.

The free-burning arc furnaces have found favour, especially for work where it is desirable to avoid any chemical reaction between the carbon in the electrodes and the bath. They have a decided advantage in giving the means of heating the cold furnaces without the introduction of any charge and by the arc only.

On the other hand, they have the disadvantage that, as soon as the bath is formed, the heat is transmitted to the surface only and no circulation is set up in the molten metal.

Many furnaces of this type have suffered from defective mechanical construction. On that ground some users have preferred direct arc furnaces, in spite of the disadvantages of heavy and cumbersome electrodes, furnace roofs pierced by large holes, and the necessity of using a source of heat other than the electric current to bring the furnace up to melting temperature.

The furnace which is the subject of this paper has been designed with a view to embodying the advantages of both the direct arc and the free-burning arc furnaces, at the same time avoiding as far as possible the disadvantages of both.

Description

The furnace is built as a circular ladle with contracted top and dished bottom. The shell is made of heavy steel plates, riveted together with $\frac{7}{8}$ -inch rivets closely spaced. The plates are perforated by $\frac{3}{8}$ -inch drilled holes, spaced about 12 inches apart and serving as vents for moisture contained in the lining. The top rim is reinforced by a heavy flat hoop riveted to the shell plates. The steel casting trunnions are riveted to the shell and rest in bearings set so as to allow for expansion and alignment. To the overhanging end of one trunnion is keyed a crank which, by means of an enclosed screw, running in oil, working in a swivelled cross-head and turned by handwheel (or, for larger furnaces, by motor) serves to tilt the furnace to any desired angle.

The bottom of the furnace is made up of a layer of coke dust and tar rammed in, supporting double layers of brick. On top of this is rammed and fixed in successive layers a hearth consisting of burnt dolomite and tar for basic operation, or of ganister in case the acid process is adopted. Supported and resting on the firebrick, outside the hearth, is placed a circular lining backed by a heavy insulating layer of asbestos sheet and formed of circle-bricks laid with ground joints and thin mortar. This lining may be made of magnesite brick for basic process, or of silica brick for acid process. In the lining are placed on the same vertical lines two holes for each pair of electrodes, and one door opening which serves both to charge the furnace and to pour the steel. For larger furnaces one tapping hole and two charging doors would be a better arrangement.

On top of the contracted top of the side lining rests the dome-shaped roof built of basic or acid brick fitted in a circular steel frame, forming a rigid skewback. The roof joint is made of a layer of powdered dolomite or ganister

spread on top of the side wall. The roof can be removed by crane without delay, and replaced by another preheated roof held in readiness to take its place. As it is found that the portion of the roof opposite to the arcs is affected more readily than the portions nearest to the electrodes (which is protected to a certain extent by the shadow of the latter) the roof can be turned round to any angle desired. Thus, when the weakest portion is getting thin, the life of the roof can be prolonged by exposing to the fiercest heat the section of the roof hitherto more protected.

It is also possible to charge the furnace through the top by removing the roof while the charge is put in place.

Electrodes

The electrodes are graphite or carbon electrodes, of cylindrical form, extended as they are burnt away by screwing a new section of electrode to the rear end of the electrode in operation. The joint is made by threaded dowels of graphite. The electrodes slide through water-cooled electrode holders made of steel pipes welded to rings at the front and back ends. Nozzles for water supply and discharge are tapped into these rings, and are connected with rubber hose to the water mains. The electrodes are wrapped in sheets of asbestos, mica, or fibre, and are thus insulated from the furnace body.

The electrode cooler with its insulation is placed between the fixed upper and sliding lower jaws of a clamp which is pivoted to a frame bolted to the furnace shell. A wedge placed beneath the lower jaw of the clamp causes it to grip and firmly hold the insulated cooler with the electrode sliding through the same.

The top part of the clamp is extended outward forming a support and U-shaped guide for the slide which grips the rear portion of the electrode. In the hollow interior of the U-shaped guide works a screw which engages against a nut held in place by prongs extending from the electrode holder. If the screw is turned, the electrode holder is moved toward or away from the furnace, advancing or retiring the electrode. The upper portion of the electrode holder is insulated from the grip by a sheet of fibre. The lower swivelling portion of the grip is closed and tightened by an eye bolt with hand-wheel nut. Both halves of the grips are water-cooled, and are fed through nipples connected to the water mains by rubber hose. Both grips are made with an extending wing, to which is bolted the bronze cable socket which receives the end of the cables, transmitting the current from the switchboard to the electrode. Both the swivelled guides are adjusted in a vertical sense, controlling at will the inclination of the electrodes.

Electric Arrangement and Wiring

The number of electrodes proposed is as follows:—
For a furnace hearth

- up to 3 ft. 6 in. diameter, 1 pair
- from 3 ft. 6 in. to 5 ft. diameter, 2 pairs
- from 5 ft. to 7 ft. diameter, 3 pairs
- from 7 ft. to 9 ft. diameter, 4 pairs
- from 9 ft. to 11 ft. diameter, 6 pairs.

This number can be modified according to circumstances.

The electrodes should be preferably of graphite, varying from 2 inches up to 6 inches diameter, according to the size of furnace and the amount of current. Each pair of electrodes enters the furnace in the same vertical plane, but at different and adjustable angles.

The upper electrodes are supplied with current. The

*Before the I.E.E.

lower electrodes, as well as the furnace body, (and, if the furnace is going to be used largely for refining work, a bottom electrode bedded in the hearth) are connected with the common of the transformer, or earthed.

For a one-pair furnace, direct current or one-phase alternating current is used.

For a two-pair furnace it is preferable to employ two-phase current, generally obtained by three-phase transformers arranged in Scotts coupling.

For a three-pair furnace, three-phase current is used, one phase being coupled to each upper electrode.

For furnaces with more than three pairs of electrodes, groups of two pairs are coupled in parallel; therefore, a four-pair electrode furnace uses two-phase current, whereas a six-pair furnace should be supplied with three-phase current. If for any reason it may be found desirable, the upper electrodes can be earthed, and the current can be supplied through the lower electrodes. A bottom electrode bedded in the hearth may be used or not. It is useful when refining because, as the lining material gets very hot, it becomes a good conductor and passes the current through the bath into the bottom electrode when using the direct arc.

The pressure of the supply should preferably be transformed to 100 volts which, by plugs on the transformer, may be reduced at option to 80 or 70 volts.

The connections for a two-pair furnace are shown in Fig. 1. To avoid any chance of shock to operators, it is advisable to place a wooden operating platform over the floor at the

Fig. 1.—Diagram of wiring of a two-pair Sahlin furnace.

FIG. 2.—Direct arcs observed with different positions of electrodes.

back of the furnace around the electrodes. All the electrodes are distributed around the half of the circumference of the furnace opposite to the tapping hole and charging doors. For the smaller sizes of furnaces, the electrodes are fed forward by hand-wheels.

The current taken is observed by reading kilowatt meters placed on a switchboard suitably located, and receiving the feeders from the transformers. It seems to me an advantage to provide choke coils to steady the current.

Assuming that the furnace is to be used for melting and refining steel, the first operation is the heating of the furnace

to the proper temperature. This is effected by turning on current and gradually advancing the points of the convergent electrodes of each pair until an arc is formed. Experiments have proved that as long as the points of the electrodes are at a certain distance from each other an arc is formed between the two electrodes. As the electrodes approach each other this arc bends outward, forming a loop. If the distance is still further reduced, the loop breaks and the arc rushes forward, sweeping downward toward the surface of the metal like a broom. If the top electrode is advanced downward (see Fig. 2). The form and direction of the arc can easily be modified by altering the angles of the electrodes and their relative position to each other. The free-burning arc heats the furnace while empty.

The second operation would be the charging. When the furnace is heated, current is taken off, and the electrodes are drawn toward the back wall of the furnace to prevent their being injured, while the material to be melted is thrown or pushed into the furnace through the charging door, or eventually through the furnace top, the roof having been removed. As soon as the charge has been placed in the furnace, the electrodes are advanced. Experience has shown that numerous momentary arcs are formed between the upper electrodes and the charge, but as this latter is melted away in the vicinity of the electrodes, the regular free-burning "broom" arc is formed between the two electrodes and the working of the furnace settles down to normal. The radiation and reflection caused by the free-burning arc are most effective for rapid melting. As, however, the bath is formed, this kind of arc reaches only the slag-covered surface of the metal, causing but little circulation in the interior of the bath. At this point, therefore, in the free-burning arcs are broken by the retirement of the lower electrodes and a direct arc is formed by the advancing of the upper inclined electrodes toward the surface of the slag. If the bottom electrode is employed, the current will penetrate toward this bottom electrode which is earthed. The furnace is now working on the lines of a Girod furnace, and creates an electric arc which causes a rapid circulation in the bath and direct transfer of heat to the metal.

In furnaces with more than one pair of electrodes, it is possible to have some of the electrodes produce a direct, and some a free-burning arc, thus making use of the effective radiating and reflecting action of the free-burning arc, at the same time as the bath is agitated by the direct arcs.

Special Work

For use as a heating furnace for very high temperatures such as are required for the production of graphite, for the calcining of magnesite, for the crystalizing of bauxite, for special crucible work, and for other similar objects, it is proposed to suspend the furnace shell containing the side walls and roof with the electrodes and the electrode mechanism from four lifting rods, operated by electric motor, hydraulic cylinder, or windlass. The bottom of the furnace which for this work does not require any bottom electrode, would be placed on a truck. On this portable bottom would be placed, in proper arrangement, the material to be heated. The loaded truck being placed beneath the furnace body, this would be lowered on to the truck enclosing the pile of material. A free-burning arc would now be started between the electrodes in each pair, and the furnace would be brought up to the required temperature. The material having been thoroughly heated or calcined, the furnace body would be lifted from the truck, which would be run away to give place to a second truck loaded with fresh material. The loaded trucks could be preheated in a gas-fired furnace before the bottom was placed under the electric furnace. This procedure has been described only as an indication of a use for the electric furnace, filling a long-felt want, but

the actual arrangement of the plant would, no doubt, be different for each case and should be separately studied.

Advantages

It will be found that the furnace, as above described, is of a very strong construction—rigid, simple, and durable. All the surfaces of the brick linings are convex, and the walls will, therefore, be held in position. The surface of the melting room, confined by spherical and cylindrical walls, is the smallest possible for the largest volume, and the amount of brickwork in the furnace is therefore reduced to a minimum. The electrodes are easily secured in place, adjusted, advanced or retracted by means of hand-wheels. There are no bolts or nuts manipulated by wrenches used in the adjustment of the furnace, every operation being carried out by hand-wheels or cotters. The roof is solid, without

any openings, removable and exchangeable in a minimum space of time. The furnace can be run either with free-burning arcs, with direct arcs, or with free-burning and direct arcs working simultaneously side by side. Changes are made without cutting off the current.

When the furnace is employed as a free-burning arc furnace no chemical reaction between carbon of the electrodes and the bath takes place. The overhanging length of the electrodes is comparatively short, and the arcs are formed fairly close to the circular furnace walls, being directed inward and downward toward the centre of the furnace.

The Sahlin furnace has not yet been placed on the market owing to the difficulty of obtaining a permit for its construction during the war, but a furnace is now being built in Great Britain intended for the production of steel ingots and castings.

The Problem of the Electric Railways

By L. A. Herdt, D. Sc.*

Electric railway transportation stands face to face today with the greatest crisis in its history. This crisis is not due to some new competitor bidding for the first place as a common carrier; the electric railway is, and will be for some time the most economical urban and suburban carrier; jitneys, busses and others will not succeed against it. The crisis is a financial one and the problem of today concerns the method of saving an industry whose entire economic basis has been undermined.

In 1918, 4,900 miles of electric railways, more than 1/10th of the total mileage in the United States, went into receivership, representing a value of more than \$500,000,000, and 750 miles of electric railways abandoned their service, representing a value of \$80,000,000.

A great many electric railway properties have grown weary from hope long deferred and are considering dismantlement at present day scrap prices rather than prolonged existence as losing ventures.

Brooklyn Rapid Transit with 755 miles of track and a funded debt of \$120,000,000 and 75½ millions of outstanding stock is in the hands of a receiver. A fare of 8 cents is in effect today and has so far proven insufficient to pay the cost of service. The Pittsburgh Railway operating 605 miles of track is in the hands of a receiver. Hundreds of others could be cited. Roads which before the war were considered the strongest financially in the country cannot any longer withstand the economic conditions which face them.

Face to Face With Bankruptcy

The suggestion is sometimes made to the effect that the companies should carry on their own burdens by borrowing money, if the street car operations are now unprofitable. Let anyone go out and attempt to borrow money on an afflicted company's credit. Credit only comes from prosperity.

The whole structure of the franchise relationship between the electric railway and the various communities has broken under the strain of war. The rapid increase in the cost of everything which is used in operating street railways, the extraordinary demands of labor for high wages, made necessary by the rise in the cost of living, the alarming decrease in the purchasing power of the dollar, has brought the electric railways face to face with bankruptcy. The fundamental fact exists that under the present costs of material and labor, the majority of the street and interurb-

an railways are furnishing, in response to the demand of the public, a service which costs more than they collect in fares.

Electric railway fares or rates are in the majority of cases regulated by law, or are established by existing franchises. With fixed fares, fixed 25 or 30 years ago, no avenue of automatic escape from rising costs lays open to the electric railway industry. In fact, the electric railways have staggered for years under inadequate rates, so that in the majority of cases, their credit has been destroyed, service impaired, equipment deteriorated to the brink of destruction.

The electric railways, (not in Montreal alone) but everywhere, are asking for higher fares. These appeals have been met by a storm of rebuke. The public seems to be willing to permit this great industry to stagger on under the burdens thrown upon it with inadequate relief in the way of increased rates, while exposed to the full brunt of the extraordinary increases in cost of labor and material. The public must be brought to realize that its interest in the electric railways of the country is greater than that of the stockholders or bond holders. The electric railways must be placed in a position to continue to discharge their essential service.

Condemned Without a Hearing

The public condemns the street car company without a hearing. Why? What is this due to? I believe that the unfairness of the public is due to the public's blissful ignorance. The public knows nothing about the street car company's troubles because the street car company does not make a confidant of the public. Public utilities, like some other big interests, rush into print only when some calamity is about to befall them. They make some sort of plea. The public which is the plaintiff stands by its guns. It doesn't realize the good that the defendant has done because it has heard only the bad. The public, someone has said, is the fairest being on earth, but it must be talked to, it must be told the facts.

A community with adequate and efficient street car service is busy, growing and prosperous, while the city, large or small, which has inadequate local transportation is dull, dead or dying. Efficient local transportation, adequate to the needs and welfare of the community is imperative.

The public utility, tied by contract and franchise, with heavy financial obligations, and with definite essential responsibilities, must work constantly and continuously to fulfil its obligations—it is tied down hand and foot over long periods of time, and is held down at best to small financial re-

*Vice-chairman Montreal Tramways Commission, Montreal.

turns, yet the public calls the company impertinent and worse, if it asks for a nominal increase for its products. Food has increased 100 per cent; shelter 20 per cent; clothing 90 per cent—it is paid. But a public utility asks 20 per cent—this is impertinence carried to its limit.

Fares Sufficient to Operate the Road

It is plainly evident that whether the public shall decide to operate the street railways, whether it assumes greater control over them, or whether it allows them to remain in the hands of private investors, the unit of their fares, the price at which their product is sold, must be sufficient to operate the roads. The fares should be restored to the level which prevailed in past years. The ticket dropped in our fare boxes today bears an impress "5 cents," but as compared with the 5 cents of a few years ago, it is $2\frac{1}{2}$ cents and no more. The street railway franchise, or the statute or agreement calling for the 5 cents unit called not for an impress or a coin, but for a certain value of purchasing power. The equivalent of the 5 cents coin in the decade 1890 to 1900 purchasing power is the 10-cent fare. The purchasing power of the dollar has declined at least 50 per cent. since the early nineties. In other words, the 50 cents of that period bought what it requires \$1.00 for today.

The decreasing purchasing power of the dollar is not a product of the war alone. The war but gave it an additional, although a mighty, impetus. The various little things that we used to pay 5 cents for are now up with an advance of 2 to 4 cents—4-cent articles are now 6 cents, and 2-cent little things are now 4 cents. If we get right down to the cent, the newspaper that used to sell for one cent is now selling for two, an increase of 100 per cent. This is all fair and just, it appears, but street car fares must remain where they are—any increase will not be tolerated.

Falling Off in Net Income

Does the public pay high prices for electric transportation service? No—decidedly no. A tabulation of the income accounts of 388 electric railways, representing more than 63 per cent of the electric railway mileage of the United States and Canada, shows a falling off in net income of 82 per cent in 1918 as compared with the corresponding period of 1917. Many companies are facing actual operating deficits in spite of increased fares and increases in gross receipts.

In any other business the manager provides for increased costs by advancing his selling price. The electric railway company with fixed fares cannot do this; only when on the brink of destruction will the community admit that there is a justification for the readjustment of rates, and even then the increased fares have in a majority of cases caused a falling off in traffic and resulted in little, if any, actual increase in gross revenue.

Is there a remedy for the conditions facing public utilities today? Let us see how the cost of street railway service is made up. Cost of electric transportation service is made up of three main items:—

1st.—Cost of operation, including platform wages (motormen and conductors), power for the cars, heating and lighting and taxes.

2nd.—Maintenance and renewals of the system as a whole.

3rd.—Fixed charges, i.e., interest on the moneys invested in the system, including city rental for use of streets.

In the city of Montreal, for the period from July 1st to December 1st in the year 1918, the operating expenses per revenue passenger were in round figures 2.6 cents, or 58 per cent. of the revenue. For maintenance and renewals, 75 cents or $\frac{3}{4}$ cents per revenue passenger was spent, that is 3.35 cents or 75 per cent. of the revenue was disbursed for operat-

ing expenses, maintenance and renewals. For this same period the average return per revenue passenger was 4.45 cents. Of the remaining 1.1 cents average return per revenue passenger, 1 cent in round figures is required to meet the financial obligations of the company; that is, to meet the interest on the bonds and debentures, leaving 0.1 cents or a little over one-tenth of a cent per revenue passenger to meet the city rental and shareholders' dividend. In other words, in the last six months of 1918, 75 per cent. of the fare collected was paid out by the company for operating, maintenance and taxes; of the remaining 25 per cent., 23 per cent. went to interest on bonds, mortgages and debentures; the remaining 2 per cent. goes to the city, the balance, if any, to the shareholders.

10 Per Cent. Increase in Wages Would Wipe Out Dividends

Of the total revenue in 1918, not less than 38 per cent. went to labor and 37 per cent. to material. In the year 1918, over \$3,000,000 was paid in wages; less than 1/10th of this was paid to shareholders. An increase of 10 per cent. in wages would therefore wipe out all dividend payments for one year.

The Montreal Tramways in the year ending June 30th, 1914, just prior to the war, spent in operating expenses including maintenance and renewals 58.89 per cent. of its revenue. In 1918, as stated above, the operating expenses including maintenance and renewals amounted to 75 per cent. of the revenue. It may also be stated that the expenditure for maintenance and renewals was below the average spent in previous years.

Increased wages and increased cost of materials are responsible for this large increase in operating cost. Municipal ownership is urged by many as a panacea. One year of municipal ownership of railways in the United States has proved the absolute danger of such control. It should be borne in mind that whether the public operate the street railways under public ownership, or whether they are operated by officials—the servants of private investors—the unit of the fares, that is, the price at which the product is sold (in this case transportation) must be such as will be sufficient to meet the total operating costs.

The management of an electric railway is not as blind as to refuse an extension of facilities or an improved service if it is likely to bring an increase in revenues, but it costs money to run cars and certain revenues must be obtained to keep the cars running.

The real cost of service per passenger depends on the length of time that he occupies space on a car and hence the traffic conditions of high cost are:

- (1) slow average speed
- (2) long average ride.

Real Cost of Service

If we divide the company's passenger revenue per annum by the number of revenue passengers per annum we obtain the average return per revenue passenger. With fixed fares, this return per revenue passenger is constant. In Montreal, the return per revenue passenger before the increase of fares was on an average 4.1 cents; it is now 4.8 cents, an increase slightly less than $\frac{3}{4}$ cents per passenger or an increase of 18 per cent. over the previous rate of fares. For every revenue passenger carried the company now receives 4.8 cents, irrespective of the distance travelled by the passenger. The dweller in Notre-Dame de Grace or Ahuntsic, or Cartierville who rides 5, 6 or 10 miles, pays no more than the dweller in Hochelaga or St. George or St. Denis Wards, who rides only half a mile to destination.

I have previously stated that the real cost of service to a passenger depends on the length of time that he occupies

a space on a car, and hence the traffic conditions of high cost of service are:

- (1) slow speed;
- (2) long average ride;

The largest single item of expenditure is labor as it absorbs from 38 per cent. to 40 per cent. of the total revenue.

Speed is Important Factor

The labor charge amounts to a fixed-quantity per hour that a car is in operation, that is, the labor charge is not proportionate to the distance travelled by the car, that is, to the mileage, but the higher the average speed of the car, the lower will be the labor cost for a given distance travelled by the car. Economy demands the largest possible car mileage in proportion to car hours and this makes the speed at which cars are operated very important. Every effort must be made to increase the average speed. Not only does a high speed make the service attractive but it also makes possible lower prices. It is the speed and cheapness of operation which makes five cents rapid transit in subways and elevated roads possible.

The previous discussion has pointed out that to provide proper service the earnings per passenger must be sufficient to allow a liberal allowance for operating expenses per passenger, that is, an adequate car mileage per annum varying with the total number of passengers must be provided. Funds must also be provided for the proper maintenance and repair of the tracks and equipment. Annual fixed charges of the capital invested in the system must also be paid.

Under the new contract, the Montreal Tramways System is operated under a service at cost plan whereby the fare is automatically adjusted to meet the cost of service, including in this cost a fair return to capital invested in the enterprise.

Control of Fares to Prevent Exploitation

The new Tramways contract embodies primarily the control of the fares, that is, the control of the fares in order to prevent unreasonable profits to the company from exploitation of the need of the public for tramways service. The **cost of service principle** is embodied in this contract.

The principle of controlling the fare in order to prevent such exploitation, or in other words, imposing a limit to the profits of the company, involves in equity the provision also of means to guarantee to the company a minimum fair return on its investment. As the chances of excessive profits are removed, so the chances of loss must be minimized. It is clear, therefore, that at any time the fare must be sufficient on the average to pay for the cost of operation and proper maintenance of the system with such other legitimate charges against revenue as may be agreed on, including a fair minimum profit on the invested capital of the company.

This return is a preferred charge on the revenue of the company after paying for the operation and proper maintenance of the system. If a guaranteed return is provided, the company must allow of a measure of outside control on such deductions from revenue as have priority over this return on the capital invested. It follows, that the various items of the cost of service must be externally controlled.

In order to provide for proper service to the public, the contract provides continuous control of the car service. This necessitates the provision of sufficient cars to carry the traffic under average conditions and special provision for rush hour conditions. It is impossible to formulate clauses in a contract to provide for control of this nature; a controlling body must be empowered to order such changes as from time to time may become desirable after careful study of the traffic requirements. Apart from rush hour conditions the service bears a simple relation to the average number of passengers per car mile, carried per annum, that is, the density factor. The cost of operation and maintenance per pas-

senger varies almost inversely as this density factor. Thus a high value of this factor results in a low cost per passenger, but the cars will be crowded. At the present time, when the base costs of operation and maintenance are high, it is necessary to allow a high value for this ratio in order to keep the cost per passenger within reasonable bounds. This limit is imposed by the average fare per passenger collected. With a decrease in base costs it may be desirable to reduce this factor, giving improved service at the same maximum cost and fare.

Tolls Reduction Fund

After all the charges have been paid, viz: operating expenses, maintenance and renewals, fixed charges, city rentals, the remaining surplus is to be divided in the proportion of 20 per cent. to the company, 30 per cent. to the city and 50 per cent. to a special fund devoted to the reduction of fares. The sum total of this fund is used as the indicator of the adequacy of the fare charged to meet the charges of the company. If this fund becomes depleted due to drafts to make up shortage in the contingent reserve fund, it will be evident that the succeeding year's operation would show a further drain of reserve which would not be replenished from the Tolls Reduction Fund. All the charges against income would not be fully guaranteed for the succeeding year and since such guarantee is a primary condition of the contract, it will be necessary to revise the fare schedules to replenish the contingent reserve fund. At any time, when owing to there being a large balance to the credit of the Tolls Reduction Fund, the same being sufficient to make up the estimated decrease in gross earnings at a lower fare for a period of several years, it is provided that the controlling body may order a reduction of fare.

This method of obtaining a readjustment of fares, being based on the total of a fund to which, when any surplus exists, money is added each year, prevents the possibility of postponing a reduction of fare by excessive expenditure undertaken to reduce the annual surplus. In this respect the scheme of the proposed contract is different from any that have been in use.

It will be seen from the above discussion that the permanent controlling body is necessary. It is obvious that outside control, as above provided for, is in the interest of the travelling public.

City Partner is Enterprise

Since the city shares in the profits and responsibilities of the tramways system, it is a partner in the enterprise. It is desirable, therefore, that such controlling body should be independent of the city of Montreal and of the Tramways Company, and should be an entirely independent body. In this way the best interest of the property and of the public will be served.

The agreement provides for a proper return on the fair value of the property and guarantees efficient service to the community.

On such a basis the matter of fares readily adjusts itself and such questions as the extension of service into unproductive territory, increase of service and other questions that have caused irritation in the past will present themselves for consideration in an entirely new aspect. All unnecessary burdens and all additional burdens imposed upon the electric railways must inevitably and logically be reflected sooner or later either in the rate of fare or in the impairment of the service rendered. The familiar protests against the crowding of cars, antiquated equipment, infrequent service, poor service, transfer privileges, etc., will now come back to the car riders themselves and the remedy is obvious.

The people of Montreal or any other city can ride in discomfort or in luxury according to the bill which they are willing to pay.

Westinghouse Company Establishes Memorial Scholarships

As a memorial to the more than 8,000 employees of the Westinghouse Electric & Manufacturing Company who entered the service of the Government in the war, this company has decided to establish a number of technical scholarships. The details of the plan by which this will be done have been given out by President E. M. Herr as follows:

"Four War Memorial Scholarships will be established each year under the following general conditions—

(a) Candidates will be limited to sons of employees of the Westinghouse Electric & Mfg. Company and its subsidiaries, who shall have been employees in good standing for a period of five years.

(b) Two of such annual scholarships may be open to the younger employees of the company or its subsidiaries who have been in their service for a period of at least two years and who do not exceed the age of twenty-three.

(c) The selection is to be determined by competitive examination to be conducted annually by the company's Educational Department under the direction of the committee hereinafter provided. The examination is to take into account not only the applicant's academic training and preparedness, but due consideration will be given to personal qualifications, general character and aptitude.

(d) Scholarships will entitle the successful candidate to pursue a four years' course in any technical school or college that he may select with the approval of the committee. The scholar may pursue a course in any branch of engineering that he may select.

(e) Scholarships will be granted for one year only but will be continued for the full four years provided the scholar maintains the academic and other standards required by the college or institution in which he elects his course of study.

(f) Each scholarship carries with it an annual payment of \$500.00 to be made in two instalments.

(g) The company will establish a Memorial Scholarship Committee consisting of three vice-presidents of the company to whom shall be referred the names and records of the candidates and who will select therefrom the four successful persons, who, in its judgment, have most satisfactorily met the tests applied. The said committee will also be charged with the duty of establishing the detailed rules and regulations and such other matters of administration as have to do with this particular matter.

It is the intention of the company to continue these Memorial Scholarships from year to year but the company reserves the right to recognize changing conditions and to modify the plan or discontinue it entirely if, in its judgment, it seems wise and expedient to do so."

Montreal Tramways' Wages

The employees of the Montreal Tramways Company have been awarded a second advance in wages by a board of arbitration, which has been accepted by the men. The award will go into effect on July 1st. Under it motormen and conductors secure advances of from six to eleven cents an hour, according to length of service, while the shop workers obtain a flat increase of twelve cents an hour. All other men paid by the hour will receive an increase of 7c an hour, while those paid by the month, such as clerks, inspectors, etc., will in the case of those receiving less than \$100 per month, obtain 25 per cent. more, and those receiving more than \$100 will obtain a 20 per cent. increase. The demand for time and a half for Sundays and holidays was not granted.

Some Pertinent Questions

1. Should the citizens at large be compelled to make good annually, through the tax rate, the deficit created by the operation of city-owned utilities?
2. What percentage of the passengers carried on the civic car lines reside outside the city limits?
3. Why should the citizens of Toronto furnish transportation at a loss to these people who are not even taxpayers?
4. If the basis of Municipal Ownership is service at cost, why not charge the cost of service to those who receive same?
5. Should not the civic car lines be put on a better revenue-producing basis so that our civic officials may have a fair chance to demonstrate their ability to handle civic transportation?
6. Does not the annual deficit from the operation of the civic car lines provide one of the most potent and damaging arguments urged against municipal ownership? Is not this argument being used today?
7. If the city were to charge the present rate of fares on the proposed North Yonge Street and Mount Pleasant lines, by what amount would the annual deficit be increased?
8. Are the real advantages to the community of encouraging people to live outside the area served by the Toronto Street Railway of importance enough at this critical time to counterbalance the dangers of operation by deficit (to be made up from general taxation)?
9. Do the citizens wish the present policy of fares below cost continued?—Bureau of Municipal Research.

Personal

Mr. L. C. Haskell, of the Southern Canada Power Co., Montreal, has been elected a member of the executive of the Purchasing Agents' Association of Montreal and district.

Louis A. Kinnear, B.Sc., of the engineering staff of the Hydro-electric Power Commission of Ontario, lost his life by drowning on May 12 in Lake Jessie, near Nipigon.

Mr. E. J. Gilmour has been appointed assistant district manager of the Winnipeg territory for the Northern Electric Company, Limited. He was formerly district manager, Montreal office.

Mr. Julian C. Smith, vice-president of the Shawinigan Water & Power Co., has been elected a member of the committee of the Montreal branch of the Canadian Manufacturers' Association.

Mr. A. Stuart Pratt, of Stone and Webster, Boston, has been appointed president of the Nova Scotia Tramways & Power Company. The company have extensions and improvements under consideration.

Mr. W. Herbert Tees, formerly superintendent of the Sayer Electric Co., and electrical engineer of the Canadian Consolidated Rubber system, Montreal, has joined the sales department of the Willys-Overland Co.

Mr. F. J. Spielman, of Spielman Agencies, Reg'd., Montreal, has been elected vice-president of the Association of British Manufacturers. The Montreal branch has 51 members and the Toronto branch 40.

Mr. James Gunn, general superintendent of the Toronto Street Railway, recently passed the fiftieth anniversary of his service with the company. He was appointed secretary to the company in 1869, when the road consisted of only a few horse cars on Queen and Yonge Streets.

A deputation of the Liverpool City Council and engineers will visit Canada and the U. S. to study electric railways, lighting equipment, and electric installations. They will visit Toronto and Montreal.

The Contractor-Dealer

Electrical Contractors and Dealers of Montreal Form Association to Deal With Wages and Other Pressing Problems

The Montreal branch of the International Brotherhood of Electrical Workers have made a demand for increased wages. They have sent to the local contractors a form of agreement setting out the new scale and conditions. These provide for an eight hour day, between 8 a.m. and 5 p.m., excepting Saturdays, which is 8 to 12. A wireman is defined as one who has worked for 4 years at the business, and has passed a satisfactory examination and holds a wireman's card. An apprentice is one who has been in the business not less than three years, and who is over 16 years of age; no apprentice is to be allowed to work on a job unless under the direct supervision of a journeyman.

A firm shall be allowed one helper to every journeyman and one apprentice to every five journeymen, and he shall serve at least four years. Men sent from Montreal to work at outside points shall have their fares and board paid which shall not be less than \$10 per week, with reasonable expenses for travel. Travelling time to and from such work shall be at the prevailing rate of wages; should a man work day shift and be requested to travel at night he shall receive one day's pay, and 8 hours shall constitute a day's work. If travelling at night, a sleeper shall be provided. In the event of a sleeper not being provided he shall receive overtime wages for the time travelling.

Contractors shall furnish the necessary tools for conduit work and supply all drills, unusual types of drills, bits, hacksaw blades, rubber gloves, and all wrenches over 14 in., balance of tools to be provided by journeymen.

The schedule of pay is: charge hands 85c. an hour; journeymen, 75c.; armature winders, 75c.; helpers, 50c. Sundays and legal holidays shall be paid double time; all time after 5 p.m. until 8 p.m. at the rate of time and a half, and Saturday afternoons time and a half.

All differences arising between the parties to the agreement are to be settled by an arbitration board consisting of two contractors who have signed the agreement, and two members of the Montreal branch of the Brotherhood, the four selecting a fifth member.

On May 22nd the principal electrical contractors met to consider the demands of the men and also to discuss the question of organization. The whole position was gone over, and it was decided to form an Electrical Contractors' Association. A committee composed of Messrs. J. F. Parsons, F. Thomson, St. Amour, H. Vincent, and Henry was appointed to discuss the subject of a permanent organization, outlining the general basis of such a society, and also to consider the demands of the men and to suggest a form of agreement with the employees. This committee will report to a further meeting when it is proposed to form a permanent organization.

All the speakers endorsed the idea of an electrical contractors' association to deal with labor and other problems.

It was felt that it was only by co-operation could such problems be satisfactorily dealt with, and Mr. Parsons, who presided, pointed out that the electrical contractors of the city would only be following the lead of others engaged

either as employers or employed in uniting into an association. At the same time, it was urged that it was not sufficient to form an association—the real test of unity was to stick to it and to one another, after the association had become a reality.

The meeting was quite enthusiastic, and representatives of the largest firms in Montreal were present.

Work of Electrical Estimators' Association of Chicago

By J. O. Wingate

A few weeks ago at a regular meeting of the E. C. A. in Cleveland, the writer brought to their attention the necessity of organizing a club or school for estimators. The object of this school would be for the promotion of the social, mental and material status of members. Raise the standard of estimates to be submitted on electrical installations by the following methods:

Educate estimators in proper methods of taking material from plans and specifications. Develop standard forms for recording and pricing the various items entering into estimates. Standardize labor cost by discussion of actual conditions occurring on the work. Investigate and determine the amount of overhead percentages to be applied to any particular estimated cost of installation. Improve plans and specifications by demanding that plans show distinctive and clear symbols for each type of outlet or apparatus, and specifications to be explicit in describing the work to be installed. Educate architects and engineers as to fair compensation for alterations and additions. Discuss all other subjects that may be found from time to time to enter into or be of interest to the electrical construction business.

In estimating work there is that responsibility or confidence the contractor places in his estimator to let him compile list of material and labor for the complete installation of a building. The confidence the contractor places in this estimator gives him a chance to go out into the field to secure business at a loss or in most cases a very close percentage of profit. The very close percentage of profit is usually brought about by the estimator estimating on a number of jobs, and not being successful begins to shorten up on his rule or underestimates his labor until after a while he will land a job. This kind of estimating adds no credit to the estimator and the contractor has to suffer from the mistakes and bad judgment. I think that the estimators in organizing a school will very materially help to better conditions for electrical contractors throughout the country. I would suggest that the estimators in different localities get together with their employers and work out a plan best fitted for their home conditions. Now is the time to get together, exchange ideas, educate each other and arrive at a fair cost for installing material that the contractor may realize a fair and just profit for his work. If the estimator is successful in securing one carefully estimated job it is by far more beneficial to him and his employer than trying to get in on everything that comes along and give but little time and no consideration to what he is figuring. There is this we estimators have to contend with in ap-

proaching the subject to our employer. Your employer may say to my employer, "I don't think much of this estimating school. I have my way of running my work and if my estimator is not satisfactory to me I will let him go and get another." This privilege all contractors have, but it will not help his condition or the estimator's, for the estimator is in the same position as labor. He goes from one contractor to another seeking employment. And you are just as liable to get an estimator that is no more fitted for the position than the one you let go. So with the help of the contractors in encouraging their estimators to help one another by forming this school of development we can become more efficient and be of greater value to you as estimators.

The estimators of Chicago do not confine their membership to estimators only estimating for electrical contractors who belong to the electrical contractors' association, but encourage anyone estimating electrical construction work for an individual, a firm or company actually engaged in the installation of same. The estimators of Chicago organized without consulting the contractors and at first did not work in harmony with them, but after a few meetings had been held and they had their organization in pretty good shape they invited the contractors to attend one of their open meetings. The working conditions of the estimators' association along with data, etc., were presented to each contractor and explained how same could be brought about for the betterment of both parties concerned. How they would educate the estimator and in educating the estimator would be of great benefit to the contractor. To-day the electrical contractors of Chicago think the Estimators' Association far exceeds any other association in the city of Chicago. And several electrical contractors, doing their own estimating now belong to the same. They have a very complete list of estimating data which they are willing to distribute to electrical estimators at about the cost price of same. Also their report on labor data, which was presented at the National Convention of Electrical Contractors and Dealers in Cleveland last July.

Have You a Fixed "Policy"? Do You Follow It? Do Your Employees Know About It?

Every business man should have a "policy," which governs his operations. This does not except the contractor-dealer. By this we do not mean a very general and hazy plan of operation but rather a definite written-down policy that every man, woman and child in the organization can read, and which will form a guide for their daily activities. About as definite an outline of a working policy as we have seen is published by the Society for Electrical Development in the last issue of their Sales Service magazine. This particular outline is attributable to Mr. Wm. J. Share, a New York electrical contractor, but it is applicable with minor adjustments to electrical contractors in other cities. Following are the policies adopted by Mr. Share with respect to (1) competitors, (2) customers, (3) employees, (4) purchases, (5) bank, (6) Business—Selling, productive, financial, administrative.

Policy with respect to Purchase: (1) I buy on Quality, net price, (2) I prefer advertised merchandise, (3) Selling concerns must have excellent and intelligent help, (4) Prompt deliveries, (5) Promises must be kept, (6) Assistance in case of emergencies, (7) A liberal Policy in adjusting errors and complaints, (8) Goods checked before shipment, (9) High grade guaranteed goods, (10) All bills are discounted, (11) Purchases are concentrated to one firm in each line.

Policy with respect to my Bank: (1) To consult them on all matters financial, (2) To consult them regarding doubtful accounts, (3) To maintain a fair balance, (4) Never to

overdraw my account, (5) To send them financial statements twice a year.

Policy with respect to my Employees: (1) To engage a high grade of help, (2) To pay a fair salary and expect a fair return, (3) To treat them with consideration, (4) Not to expect something for nothing, (5) To offer constructive criticism instead of destructive criticism, (6) To give them steady employment, (7) To let them know their services are appreciated.

My policy with respect to Competitors: (1) To consider them as honest men engaged in an honest business, (2) As willing to help me out in emergencies with help or informa-

Are you prepared for the hot-weather-Fan season? Plan your campaign now.

tion, (3) To work with them in an effort to improve conditions in the business through associations, (4) To speak well of them on all occasions.

My policy with respect to Customers: (1) To make good on all promises, (2) To treat them with courtesy at all times, (3) Not to take advantage of their ignorance of matters electrical, (4) To handle their complaints with despatch, (5) To keep their equipment in continuous operation, (6) To be liberal in adjustments of defective material and workmanship, (7) To give them the benefit of any doubt, (8) To deal only with high grade concerns of good standing and reputation, (9) To maintain pleasant relationships, (10) To collect accounts promptly when due.

My policy with respect to the business of Selling: (1) To believe in the efficiency of advertising and to advertise, (2) To sell on a Quality Basis, not Price, (3) To sell my goods and services only to high grade and reputable concerns of good standing, (4) To make my proposals complete in every detail, covering a description of materials furnished, time of installation and delivery, price, terms of payment and guarantees, (5) Not to depend on verbal orders, (6) To depend on recommendations of satisfied customers in obtaining new work, (7) To make no promises or statements that cannot be kept, (8) To keep a record of all proposals prepared, number accepted, number lost and reasons why.

My policy with respect to Financial Matters: (1) To maintain and operate a good Cost Accounting system for the purpose of determining (a) The financial condition of the business at any time, (b) The progress of the business from time to time, (c) Amount of accounts payable, (d) Amount of accounts receivable, (e) Profit or Loss on each job, (f) Monthly and yearly overhead charges. (2) To collect accounts receivable promptly, (3) To pay accounts payable promptly, (4) To set aside a certain percentage of gross income for reserve for (a) Bad debts and other contingencies, (b) Advertising. (5) To earn a net profit of 10 per cent on gross amount of business done, (6) To reinvest profits in the business, (7) To accept no work unless a profit is shown.

My policy with respect to Installation of Equipment: (1) To supply competent and reliable help, (2) To start work promptly and carry it through without intermission or delay, (3) To leave no part of the work unfinished, (4) To maintain the highest standard of workmanship and material, regardless of inspection, (5) To prepare careful and complete estimates on all proposals submitted.

My policy with respect to my Business: (1) To subscribe to all trade journals, (2) To join all associations pertaining to my business, (3) To participate in all their activities, (4) To increase my acquaintance with the best men in the business, (5) To regard the business of electrical contracting as a good business and one worthy of the highest and most intelligent effort.

Whose Duty is it to Develop the Electrical Industry? Who is Doing it? The Contractor-Dealer's Course is Clearly Marked Out

By Samuel A. Chase

So much has already been said on the subject of co-operating and various methods suggested to improve all branches of the electrical industry that it is difficult to say anything new, but possibly the same old story repeated will gradually have its effect, and already we can see a marked improvement along all lines, principally in the way of better merchandising methods on the part of the Contractor and Dealer.

In some districts the Contractor and Dealer have been alive to the situation and opportunity offered and have profited by the wave of enthusiasm which has awakened the entire industry through the efforts of Mr. Goodwin and have either opened new stores or enlarged and improved old stores and are selling incandescent lamps and various electrical appliances with profit to themselves and convenience to the buying public.

In other localities the Contractor-Dealer has not been alive to the situation, and Central Stations as well as the buying public complain that advantage has not been taken of the opportunity given by the central stations and the manufacturer, and incandescent lamps or electrical appliances are not sold in attractively arranged stores located conveniently for the buying public.

Central stations, backed up by the manufacturers, are realizing that to retail incandescent lamps and household appliances, excepting on a strictly business basis, taking into consideration the cost of doing business and the maintenance of a retail establishment, is the height of folly and disregards the ethics of the Electrical Industry in that it does not follow the slogan of "Live and Help Live" because it does not recognize the service rendered by the Contractor-Dealer and his cost of doing a legitimate retail business.

But, gentlemen, the Contractor-Dealer must respond and meet the situation and arrange attractive retail stores, located conveniently to the buying public; otherwise, the central station, the jobber and the manufacturer will seek other channels of distribution—possibly selling direct or through distributors outside the electrical industry.

The Dealer Must Be a Merchant

One of the principal criticisms of the Manufacturer in the past has been that **the average contractor-dealer does very little to create a demand for the sale of household and other electrical appliances to the consumer.** In other words he has not been a merchant.

If the Contractor-Dealer will become a real merchant, there is no department of selling in which the manufacturer and jobber will not be ready and anxious to help him. Suitably advertising matter will be furnished; salesmen instructed and attractive window displays suggested and the manufacturer, jobber, central station and contractor-dealer will go hand in hand down the road of business prosperity.

I believe it pertinent at this time to emphasize that the manufacturers believe that the electrical dealers as a rule have not been as active as they should be in the sale of motor driven devices and there is a great possibility in this field.

Take for instance, six of the commonest electrically-operated machines used in the home—the washing machine, the sewing machine, the ironer, the vacuum cleaner, the fan motor and the polishing and grinding motor. All of these classes of apparatus have been developed to a high degree, are manufactured in very large quantities and should be universally used wherever electricity is available.

The fact that electrical dealers have overlooked this pos-

sibility is noticeable since a number of new concerns have sprung up who do nothing but handle devices of this kind, adding to their line a full line of heating apparatus. Such dealers can now be found doing a profitable business. Their stock in trade consists of an attractive display room in a district frequented by women on their shopping tours, generally some advertising, and in some instances, solicitation through the residential district.

The electrical dealer has been slow to get into this particular field and I believe that in order to handle devices of this kind, he must have an attractive store, he must be in a position to do extensive solicitation, considerable newspaper advertising, and render service, from time to time in connection with such devices as he has sold.

It is true that either an attractive display room or else a system of house to house canvassing with samples furnished free of charge is necessary. Newspaper advertising has also been effective, if the advertisements are properly timed and carefully prepared. The question of service is furthermore necessary, but successful electrical dealers make their service feature one for building up additional business. In other words, their service men who go to repair or adjust any device sold, open up sales for other classes of apparatus. They distribute literature and report prospects to the office, which are followed up systematically and energetically.

A good illustration of this service feature is that pursued by a concern out west which has recently put on the market a farm lighting outfit. The sales organization of this company feel that they are just starting when they sell the farm lighting outfits. They follow up the prospects with all sorts of electrical devices, such as fans, house pumps, washing machines, ironers, sewing machine motors and small motors for general power purposes. Their prospect becomes a regular customer for lamps. He undoubtedly will make extensions in time in his wiring and will require supplies. Thus, they become the sole supplier of the farmer's needs along electrical lines. If more of the electrical dealers would pursue a policy like this they would, undoubtedly, build this business up enormously.

It would pay the electrical dealers to get in touch with the manufacturers of small motors and electrically operated devices used in the home. On the most expensive of these, extension time payment plans are now worked out which enable the householder to finance purchases which he could not think of financing if he were required to raise the necessary cash.

This is a time of great economy. There are many tens of thousands of electrically driven washing machines being sold each year and this number is increasing in spite of the increased cost of living, due solely to the fact that they are reliable labor service. Many women are dispensing with their laundresses and either handling the washing machines themselves, or doing so through the maid of all work they usually employ. This means a direct weekly saving which will pay for an electrically-driven washing machine and ironing outfit before many weeks pass by.

Likewise, in the sewing machine motor, there never was a larger demand than there is at the present time in connection with a large amount of clothes that are being manufactured and the enormous amount of Red Cross work which is being done. These same arguments apply to the other devices I have named, and there is no question in our minds but what the next two or three years are going to show an increasing demand for labor saving devices.

The electrical dealer has not been alive to this situation in many localities. Manufacturers have had to establish their own branches for retailing these electrically-driven devices, and a special class of dealer has sprung up simply because the electrical dealer has not realized the opportunity and modified his business methods to meet this new condition.

*At meeting of Connecticut Association.

Several dry goods stores as well as hardware and other retailers outside the electrical industry have profited by this opportunity during the past few years and materially increased their electrical departments.

Electrical manufacturers and manufacturers of motor-driven machines used in the household have worked out quite extensive selling campaigns based on experience gathered in the field, which is all furnished to the electrical dealer gratis, as well as other literature and sales helps.

I don't know that I blame the contractor-dealer for not going into the retail business excepting in the recent past because as you know until recently there was no stability in prices—in other words, the service rendered by the retailer in carrying stock and operating a retail establishment was not recognized; but now under the new order of things the manufacturer, the jobber, and the central station recognize the service rendered by the contractor-dealer and all desire to co-operate.

In recent talks during meetings of your various local associations I have mentioned a new slogan "Live and Help Live" which I believe is preferable and better, fitted to the electrical industry than "Live and Let Live"; but I have been wondering if the industry as a whole is in an attitude of mind to follow the slogan "Live and Help Live" and if not ready at this time to do this, further educational methods are necessary before a definite plan of merchandising which will safeguard the best interests of all can be put in operation.

What I mean by this is, is the contractor-dealer ready and willing to do his part and become a real merchant, co-operating with the jobber and manufacturer and establish attractively arranged retail stores, and assist in every way in this great problem of distribution of electrical appliances from the manufacturer and jobber to the consumer, co-operating with them and with the central station?

Is the manufacturer, the jobber, and the central station management in the right attitude of mind to realize the importance of the contractor-dealer and the service he renders in this problem of distribution to the ultimate consumer to co-operate in every way and make it possible to distribute these products on a proper business basis?

All classes in the industry with few exceptions seem to be impressed with the desirability of adopting this slogan or "Live and Help Live" and it is up to each and every one of us to do our share. We desire to learn the contractor-dealer language; so we can thoroughly understand it.

I do not believe that any branch of the electrical industry has at any time been disposed to deprive the contractor-dealer of the right and opportunity to transact a retail business on a profitable basis, but the difficulty has been in the past that the manufacturer, the jobber or the central station has not fully understood your problems, and could not talk in your language, neither did the contractor-dealer fully understand their problems; so that it has become necessary and always will be a necessity for all classes to get together and discuss these problems in open meetings. This is being done in many districts, and joint meetings of all classes have been held with great success, whereas previously the jobber, the manufacturer, the central station as well as the contractor-dealer, would each hold their meeting behind closed doors inviting no one excepting members of that particular branch of the industry—therefore, very little was accomplished in the direction of co-operating as in a spirit of "Live and Help Live."

Change is the fundamental of economic progress. To recognize and accept the probability of a change is one-half of the problem; to see its direction accurately provides the ultimate solution, and we believe there is a changed condition the result of which is already showing great benefits to the industry as a whole and particularly to the contractor-dealer.

Why not discuss and formulate definite plans and appoint active committees on such subjects as:

A—House wiring campaign throughout the provinces, including time payment where necessary.

B—The establishment of retail stores.

C—The selling of electrical appliances such as vacuum cleaners, washing machines, sewing machine outfits, and other electrical appliances on an installment plan of payment.

D—Devise ways and means to so wire the kitchen and the dining room that such appliances as irons, percolators and toasters can be easily and safely used. Many now are using their appliances simply as ornaments on the dining room sideboards because of the fact that proper outlets are not provided enabling the housewife to easily and quickly use them without disturbing the lamp in the fixture over the dining room table, and the cords suspended over the table are unsightly and the ordinary wiring as you know is inadequate.

E—Divide your territory and large cities up into zones and place active sub-chairman in charge of each zone who will carry out the plans of the general committee in the endeavor to increase business and co-operate with other classes in the industry.

F—Appoint a committee to meet committees of other Associations, such as jobbers, manufacturers, and central stations with a view to establishing closer relations and as an inspiration to get together and keep together.

Hold meetings together and leave the door open at all meetings.

Selling Up, and Selling Down

By Sidney New

When you buy a tooth-brush at the drug store, the clerk is more than apt to suggest a tube of tooth paste. When you buy a collar at the haberdasher's, the clerk will suggest a new tie or a shirt. The least that any store clerk, in a mercantile line, will do is ask "Is there anything else?"

If you ask to see a two-dollar shirt it will be shown you, but the clerk won't stop there—he will bring out some three-dollar ones, and five times out of six you buy the more expensive one.

Processes such as these are called "selling-up." They require some tact and skill, but they result in increasing sales from fifteen to fifty per cent, without increasing selling expense, and therefore, in some lines of business, double the profits.

But, what would you think of a store-clerk who, when you asked to see a three-dollar necktie suggested that you buy one for two-bits. If you went to buy a desk for your office and had picked out one you liked and the salesman suggested that you take another with half as many drawers and with rough splinters along the edge, saving \$6.23, would your opinion for that store rise very high? It would not.

You never experienced the process of "selling-down" because "it isn't done"—except in the electrical business. And there it is done with a vengeance.

Mr. Ownahouse wants his house wired. He sends for John T. Wiringman, a reputable contractor, to figure the job. John T. figures a centre outlet, a side outlet, and a snap switch outlet for every room in the house—he knows if he puts in any convenience outlets, the figure would be, oh, very much too high. Ownahouse gets the figures and whistles. "I didn't know," he says, "that it would cost so much."

Right there John T. gets nervous about the knees. Does he explain that the figure is reasonable, that he was even about to suggest additional floor outlets in the dining room for table appliances, extra outlets in the bedrooms for curling irons, warming pads, radiators and other conveniences,

in the sewing room for a sew-motor and an iron, and in the bathroom for a radiator, and so on? Does he "sell up" as the cheapest clerk in a store would?

Not if he is the John T. Wiringman that we have met. His first suggestion is that Mr. Ownahouse may be able to get along without side lights in the bedrooms. Then the centre outlet in the kitchen goes. Next goes the bathroom switch. Finally the customer gets a job at about one-half the original figure, that isn't much of a job.

Next week Mr. Ownahouse buys a toaster-stove. If he could use it conveniently, he would add a percolator and a number of other appliances. His wife cannot use her iron without turning off her light. The result? One of two

**Plan your window display of Electric Fans.
Let people know where to buy them.**

things—either Mr. Ownahouse gives up the use of electricity in disgust using it only for light, or if he has abounding faith he brings a so-called "electrician"—not the reputable John T. Wiringman—has the convenience outlets installed without reference to Underwriter's rules, and tries to be satisfied.

Who suffers when John T. skins down his figures? First of all John T. suffers, because he has reduced the volume of his business and reduced the profits he ought to make.

Second, John T. suffers because Mr. Ownahouse blames him for not providing enough outlets.

Third, John T. suffers because he loses the possible sale of electrical appliances that would just fit the missing outlets.

Fourth, the customer suffers because he cannot avail himself of the electrical conveniences he should be able to use.

Fifth, the central station suffers because it loses the increased revenue without increased capital investment it ought to enjoy through Mr. Ownahouse's meter.

Sixth, the whole electrical industry suffers. It has received another black eye.

And who gains? Possibly the "so-called" electrician.

Vancouver Convention an Important Event

The electrical convention of the Vancouver Association of Electrical Contractors and Dealers on May 26th and 27th, was a splendid success and will be reported fully in our next issue. The programme included addresses by W. L. Goodwin and S. A. Chase; also Wm. McNeill, assistant general-manager Western Power Company; W. G. Murrin, assistant general-manager British Columbia Electric Railway Company; F. Jno. Bell, general-manager Canadian Wire & Cable Company; R. E. Callahan, manager Toronto branch Majestic Electric Supplies, Limited; H. B. Kirkland, general-manager American Conduit Company; Frank T. Groome, sales-manager Benjamin Electric Manufacturing Company; A. S. Edgar, special representative C. G. E. Company; A. J. Soper, distribution-manager Northern Electric Company. The arrangements were in charge of the following committees:

Organization Committee: Jno. Read, E. A. Walker, S. E. Jarvis, J. E. Rowland, C. Moulton, J. J. Crossman, R. A. Graham, J. Duck, S. R. Smith, E. Brettell.

Finance Committee: C. H. E. Williams, F. Williams, H. Rees, J. E. Rowland, E. Brettell.

Reception Committee: Every member of the Vancouver Association.

Mr. and Mrs. E. G. Mundy kindly consented to take charge of the arrangements for the entertainment of the ladies.

Electricity in the Largest Hotel in the World

The new Hotel Pennsylvania, at the Pennsylvania Terminal, New York City, has 2,200 rooms, each with its bath, and is the largest hotel in the world. It was also planned to be one of the most modern, convenient, and comfortable, and consequently electricity plays a large part in its service to guests. Special precautions have been taken to prevent the

Electrically operated potato peeler

failure of the supply, arrangements having been made to supply current from three independent sources—from two stations outside of the building and from a generator inside. The lights are operated from three separate circuits, and some of the lights in each corridor, and at other emergency points, are lit from each of these circuits so that even if

Ice is finely chopped by electric motors

trouble developed on two circuits at the same time, no important part of the hotel would be plunged into darkness.

The guest is constantly meeting novel applications of electricity. When he enters his bath-room, the first thing he notices is a faucet, labelled "ice water," which is supplied by an electric pump in the basement. Should he order his breakfast served in his room he receives it in a surprisingly

short time, and the secret of this rapid service is the electric breakfast kitchen located on every one of the guest floors. These kitchens are equipped with electric coffee percolators, stoves, toasters, egg-boilers, and other cooking utensils. Each one also has a "cold box," or refrigerator, set in the wall and kept cold by refrigerated brine circulated by an electric pump.

The air in the restaurants and other concourse rooms is fresh and pure in spite of the many people and the smoke from hundreds of cigarettes and cigars. This is due to the fact that air for these rooms is drawn in from the outside by electric ventilating fans, forced through cheese-cloth filters, washed in running water, and heated in winter and cooled in summer; the foul air is drawn out by exhaust fans. Each of the 2,200 bath-rooms is also ventilated by exhaust. Twenty seven Westinghouse motors operate these fans, and 800 tons of sheet metal were required for the ventilating ducts.

Two twenty-horse-power motors drive vacuum cleaners that draw dust and dirt from 487 openings and carry it through a total of three miles of pipe to dust receptacles in the cellar.

Electric Kitchen and Laundry

A trip through the kitchen and other service departments brings to light many other interesting tasks performed by

Motor-driven chopping machine.

electricity. There are electrical grills and ovens, electrical potato peelers, meat choppers, cake mixers, and dishwashers. There is also an electric machine that cuts ice into cubes for the water glasses, crushes it for iced drinks, and "snows" it for cooling bottles, etc. The laundry, which is one of the largest private laundries in the country, is electrically operated throughout.

Perhaps the most unique electrical machine is the one that reproduces writing and is used to convey instructions throughout the hotel. These machines can be seen in operation at various points, and to watch the pen of one of them busily spelling out a message in the handwriting of someone perhaps twenty floors below, is fascinating and somewhat uncanny.

One of the inconspicuous, but very modern, features of the electrical equipment is the switch panels for controlling the lighting circuits on the various floors. These panels differ from the ordinary type in that it is impossible for anyone operating the switches to come in contact with live parts.

Hence they are absolutely safe and can not cause injury to the operator. The fuses and connections are locked in a separate compartment and are accessible only to authorized electricians.

Ball Bearing Manufacturers Combine

Of interest to all users of bearings is the announced reorganization, effective May 1st, whereby the products of The Hess-Bright Manufacturing Company, the SKF Ball Bearing Co., the Atlas Ball Co., and the Hubbard Machine Co. will be sold through one central organization. The new company, under the name of SKF Industries, Inc., will thereby be able to offer a comprehensive line of ball bearings, including the Hess-Bright deep-groove type, SKF self-aligning radial and thrust bearings and ball bearing pillow-blocks and shafting hangers. Through the medium of its engineering organization, backed up by a well equipped laboratory, the new company will be able to place at the service of bearing users the knowledge gained in many years study of anti-friction bearings of all kinds. On request, manufacturers' problems will be analyzed in detail and that type of bearing recommended which (independent of sales consideration) is best suited to the conditions met. In addition the laboratory staff will carry on research studies affecting anti-friction bearing design and application. The new company, SKF Industries, Inc., will be under the direction of B.G. Prytz, president. W.L. Batt, vice-president, J. P. Walsh, comptroller, and S. B. Taylor, sales manager. The principal office will be at 165 Broadway, New York city, with branches at Boston, Philadelphia, Atlanta, Buffalo, Cleveland, Detroit, Cincinnati, Chicago and San Francisco.

The Henry Engineering Co.

The Henry Engineering Company announce that they have opened offices at 71 Bay Street, Toronto, where they have established themselves as consulting engineers on general engineering work. They have also opened a department at this address, which will specialize in the purchase and sale of power equipment of every kind—steam, electrical and hydraulic—both new and used. The new company will continue to handle the special agencies carried in the past by Mr. Thomas Henry, at 58 Front Street West, and will also, from time to time, add other lines of engineering equipment and supplies.

The company is composed of Mr. Thomas Henry, Mr. James A. Rumgay and Mr. Edwin B. McBryde. Mr. Henry was for many years chief engineer of The Interurban Electric Company, Limited, and The Erindale Power Company, Limited, having been solely responsible for the design and construction of the development plant and transmission system of the latter. Later he was associated with the Sales Department of the Toronto Electric Light Company, and for the past year and a half has been carrying on a general consulting and sales agency business under his own name at 58 Front Street West, Toronto. Mr. Rumgay was for some years with the Canadian Allis-Chalmers Company as draftsman and estimating engineer. More recently he has held the position of designing engineer and manager of the boiler department of the Polson Iron Works, Toronto. Mr. McBryde is also widely known. He had an extensive operating experience, covering several years in England, which was followed by a similar experience with the Toronto Electric Light Company, where he was assistant superintendent of distribution, and later assistant sales manager. For the last two years he has been manager of the Fisher Electric Company, Toronto, handling new and used electrical equipment.

Twelve and Sixteen Inch Oscillating Fans

The illustration herewith shows a six blade oscillating fan manufactured by the Dayton Fan and Motor Company, Dayton, Ohio. This style is made in 12 and 16 in. sizes and is convertible to bracket position. The company have just started work on a new \$150,000 factory building upon which construction will be rushed to completion by the end of the

Six blade 12 or 16 inch Oscillating Fan, convertible to bracket position.

summer. The plant will measure 150 feet by 80 feet and have a floor space of about 75,000 feet including five storeys and basement. The officers of the company include Mr. Charles P. Schnaus, chief engineer, with whom is associated Mr. Ward Houston, formerly production manager for the Robins & Myers Company and Mr. U. B. Unger, superintendent.

Automatic Extension Reel

The design shown in the accompanying illustration shows the automatic extension reel for electric lamps which is being placed on the Canadian market by the Cincinnati Specialty Manufacturing Co. The actual size of the reel is 9 inches in diameter by 2 inches in width, supplied with 25 feet of reinforced weatherproof cord. The head is provided with a swivel joint, enabling the lamp to be carried in any direction from the reel, and an automatic lock permits a posi-

Automatic Extension Reel—Cincinnati Specialty Co.

tive stop at any desired point. This apparatus thus allows one to take the light exactly where it is wanted, eliminating the necessity of dragging cords over the floors, breaking the insulation and increasing fire hazard. It represents an actual saving in cord, lamps, fuses and guards. The insulating features of the reel have been well taken care of, as the connections have withstood an Underwriters' Laboratories' test for 1250 volts.

The C. G. E. are putting on a big Fan campaign to help the contractor-dealers.

Conduit Hanger on New Principle

In the accompanying illustration a new conduit hanger is shown which is being manufactured by the Chicago Expansion Bolt Company. It has a U-shaped body to receive the pipe, one side of the U being provided with an expansion feature to secure it to the wall or ceiling. The maker states that the fixture costs no more than an ordinary expansion

Conduit Hanger by Chicago Expansion Bolt Co.

bolt. It is also claimed that as no other fixture with separate bolts and nuts is required it makes a material saving both in labor and material costs in fastening conduit lines. It is made in sizes adapted to all sizes of conduits and is furnished in either galvanized black or plain finish.

You have a dollar.
I have a dollar.
We swap.

Now you have my dollar.
And I have yours.

We are no better off.

You have an idea.
I have an idea.
We swap.
Now you have two ideas.
And I have two ideas.

That's "some" difference.

New "Devoe" Switch

The Devoe Electric Switch Co., Montreal, are making an improved type "A" externally operated safety service switch. The company draw attention to some unique features of construction; one is the action of the moving arms, which gives uniform motion to the switch blades, whereby the three blades enter their contacts at the same time. The square steel operating rod is designed to act only as an axle, moving the arms, and, it is claimed, is not subjected to strain or twisting which distorts the contacts and the blades of the switch in operating. Another feature is that the switches are so made to secure the high rate of 90 to 95 per cent. contact at the hinge and jaw joints.

Mr. Kenneth A. McIntyre, chairman of the Toronto branch of the Ontario Association of Electrical Contractors and Dealers, met the Brantford Association a few evenings ago and discussed with them the advisability of this becoming a branch of the Ontario Association. The matter is being further considered as the majority of members appeared favorable to affiliation.

How I Increased My Sales 100%

Most of us are unsystematic. We conceive an idea and follow it up to a certain point. Then something intervenes, or we get the idea we are not making headway and—stop. This is not the way to accomplish results.

How often can you recall cases in your sales experience where you have done a lot of pioneer work and failed to land your customer? Why did you fail? It must be because you stopped too soon. Your judgment in the first place was that your customer was a good prospect. Surely then, he was a still better one after you had worked on him for some time. Do you admit that your judgment was at fault? Of course not. Now this applies very specially to the electrical contractor-dealer. He needs to keep everlastingly hammering away at his customers until they **get the habit** of electrical appliances. Never give up—because you're **right**. Sell the electrical idea—what it means in the home.

A friend contractor-dealer of mine specializes in house-wiring—new homes for the most part. He's a gentlemanly fellow and makes a point of getting on good terms with the owner and, indeed, so far as is possible, with everyone on the job. Then when the wiring is all done, instead of going away and forgetting all about it, my friend just begins to get busy.

You all know what a muddle things are generally in on "moving in" day and often enough for several days after. Generally no range connected up, perhaps cold weather and furnace not going properly, or very hot and no electric fans, etc. Well, recently this contractor-dealer certainly cashed in on his opportunities. By keeping in touch with the house-owner, he knew when moving day arrived. It turned out to be hot and sultry. What did Mr. Contractor-Dealer do? Early in the morning he ran around to the house with a fan, a toaster, a percolator, a chafing dish, a little two-element hot-plate and a vacuum cleaner. "Help yourself," he told the lady of the house. "I know what moving is because I've moved myself."

Of course, this couldn't have been done unless the contractor had taken the precaution to have a few judiciously placed base board outlets put in previously. As it was, the lady was the most grateful person you ever saw. More than that, she had been sold the **idea** and not a single item of the list was allowed to return to the dealer, except the chafing-

dish which she replaced by a good sized range. Since that time, by still keeping in touch with this house, the contractor has sold several more articles. Just now he is installing a washing machine because he came in one day at an opportune moment when the wash lady had just sent word she was "not very well."

This policy of following up and keeping in touch with his customers is now consistently followed by this contractor-dealer, who advises me that on more than one occasion his sales of equipment have amounted to more than the original wiring job and that they carry a bigger profit.

The Ideal Commutator Dresser

To avoid the necessity of having to turn down commutators on a lathe the Ideal Commutator Dresser Company, of Chicago, manufacture an abrasive block with which they say commutators may be re-surfaced and kept in smooth running order without even taking the load off the motor. The Ideal Resurfacer is not a natural stone but a manufactur-

Dress the Commutator while in operation.

ed product of uniform density and cutting quality throughout. It is pointed out by the company that natural blocks are sometimes soft and clog easily with copper dust. By the use of this re-surfacer the Ideal Commutator Dresser Company say a seven hour job on a lathe may be cut down to one hour and better results secured. A ten day free trial is offered as evidence of their faith in the Ideal Resurfacer.

The Emerson Fan

McDonald & Willson, Yonge St., Toronto, have taken the agency of the well known Emerson Fans, recognized as standard equipment in the United States. These fans carry

a five-year guarantee. McDonald & Willson will carry a complete stock so that prompt shipment may be made at all times.

Walger Connectors

New 3-way connector for conduit connections and tap joints. Requires no tape or solder. Manufactured by Walger Connector Company.

Current News and Notes

Burlington, Ont.

The Burlington town council have contracted with the Dominion Power and Transmission Company, Hamilton, Ont., for a supply of electric energy for a further five years. It is stated the Ontario Hydro offered practically the same rates but their proposal was turned down.

Calgary, Alta.

Street railway fares in Calgary, Alta., have been increased to a straight five cents.

Edmonton, Alta.

The deficit of the Edmonton Street Railway for last year is less by about \$20,000 than the previous year. This is attributed largely to the introduction of one-man cars. Greater savings are anticipated for the year 1919 as all cars will be of this type.

Estevan, Sask.

A press report from Estevan, Sask., states that lignite briquettes will be manufactured on a commercial basis about the end of October. The Lignite Utilization Board, however, state that there is still a great amount of experimental work to be done.

Fredericton, N.B.

The annual report of the New Brunswick Telephone Company, recently submitted, shows assets of \$2,628,962; liabilities \$2,614,112, leaving a surplus of \$14,850. This is after deducting a dividend amount of \$31,869. Earnings for the year ended March 31, 1919, totalled \$649,016. Expenses amounted to \$542,097. President S. H. White, in his report, stated that it would be necessary to ask for permission to increase their rates.

Hamilton, Ont.

The Hoover Suction Sweeper Company, of North Canton, Ohio, have plans under way for the construction of a factory at Hamilton, Ont.

The Hamilton Lamp Company, Limited, have been granted letters patent. Capital stock is \$300,000 and head office, Hamilton, Ont.

Marysville, N.B.

The town council have under consideration the installation of an electric lighting system.

Montreal, Que.

The annual statement of the Montreal Light, Heat and Power Consolidated, to be presented at the annual meeting on June 5, shows a net income, after charges and depreciation, for the twelve months ended April 30, of \$3,605,181, an increase of \$16,458 over the previous year. The gross revenue for the year amounted to \$10,939,272, an increase of \$548,588. Operating expenses, however, increased by \$589,623, the total being \$5,357,492. The total surplus is \$2,608,204. Sir Robert S. Holt, the president, intimates that an increase in rates may be necessary if operating expenses continue to rise.

The Radio and Electrical Supply Company, Montreal, have registered. Mr. Wm. T. Hawes is proprietor.

The Marconi Company will erect a long distance wireless station in Montreal to handle some of its trans-Atlantic business. This station will work direct with Paris.

Niagara Falls, Ont.

It is stated that difficulties between the Ontario Hydro-electric Commission and the two thousand men at work on the new power canal have been settled amicably. A general strike was threatened.

Orillia, Ont.

The town council have under consideration the placing underground of all electric wires on the main street.

Regina, Sask.

The electric light department of Regina, Sask., shows a surplus of \$21,290 for the first four months of the year. The deficit on the municipal electric railway, however, is \$9,150 for the same period.

It is stated that the city of Regina may commence in the near future the distribution of electrical energy to some of the towns and villages within a radius of twenty or thirty miles. The town of Lumsden have a definite proposal under way to submit to the Regina city council. Such a transmission line would also serve the farms along the route.

Roberval, Que.

The town council of Roberval, Que., contemplate repairs to their hydro-electric plant, which operates under a 50-foot head. They will probably require a new turbine and generator, together with exciter and necessary switch-board equipment.

Shawinigan Falls, Que.

The town council of Shawinigan Falls, Que., have under consideration the expenditure of some \$35,000 on a new system of street lighting.

Toronto, Ont.

Mayor Church, of Toronto, has moved that a by-law be submitted to the ratepayers at the next January elections to provide for the expenditure of \$5,000,000 as a preliminary step toward taking over the Toronto Street Railway in 1921. The Transportation Committee will prepare a report on the matter.

Windsor, Ont.

The Sandwich town council have declined to adopt a by-law authorizing a fare increase for the Sandwich, Windsor and Amherstburg Railway which it was intended to submit to the ratepayers on June 14.

National Board of Fire Underwriters

gave their approval to Allen non-acid soldering fluxes after testing them for nearly two years between the time we submitted samples and the time their report was issued. And, thus far, no other soldering fluxes have been approved. Send for samples.

Young, ambitious, good organizer. Toronto district preferable. Communicate Siddall, 75 Lydyett Lane, Barnton, Northwich, Cheshire, England. 11-12

Representation Wanted

Manufacturer of Alternating Current motors wishes active representation in Toronto and vicinity. Box 936, Electrical News, Toronto.

Steel Trolley Wire Being Substituted for Copper in Los Angeles

The substitution of steel trolley wire for copper wire has just been begun by the Los Angeles Railway Company. Officials of the company state that they have been unable to obtain a sufficient supply of copper wire to care for their maintenance needs and that the price of copper wire is so high as to be practically prohibitive. They feel that steel wire is not nearly as good and as it is much heavier it requires several times as many men in its installation. Also there is no

doubt that it will prove more injurious to trolley wheels than did the copper wire. Twenty-six miles of steel wire has already and will be installed as rapidly as possible. More of this steel wire is on the way.—Electric Railway Journal.

GREATER BUYING POWER

That is what the trade paper represents to the man who is a regular and careful reader of it.

In its editorial columns he finds useful ideas that help him in his business—helps and hints that smooth out many of the rough spots—plans the other fellow has tried and found successful.

The advertising pages are also a source of valuable information. Here he learns what the manufacturer has to offer—how those goods are made—the materials that enter into their manufacture—when salesmen are on the road—special opportunities, etc.

He keeps thoroughly posted on the market, because the trade paper is in close touch with the situation and gives him accurate knowledge of conditions—when and what to buy.

Read your trade paper thoroughly each issue and make a reference file of it. You will often have occasion to refer to it.

Strong Selling Features of Durable Daytons Mean Real Profit for Dealers

Illustrating Durable
Dayton No. 676
Six blade 12 or 16 inch
Oscillating Fan, con-
vertible to bracket
position.

Durable Dayton Fans are easy to sell and good to sell because of their quality—they mean satisfied customers and repeat orders—Dayton fans are sturdily made, for long, untroubled service. They consume less current and their square-end blades deliver more breeze.

The line is complete, including electric ceiling, desk, and wall bracket models for alternating and direct current, exhaust fans and water motors. Easily adaptable; all Dayton desk fans can be immediately converted into the wall bracket type.

Opportunity to "Cash In"

Demand is for quality now, stronger than ever before—Daytons have held the fan quality leadership for 26 years, the best fan for every purpose.

Durable Dayton dealers are given co-operation; sales helps and advertising that brings in customers and profits.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

The Continued Success of Colonial Copper Clad Wire

TRADE C.C.C. MARK

is due to the perfection and continued supremacy of weld between the copper and steel, and an expert knowledge of and skill in the production and uses of high grade electric wire and cable products.

For over 10 years C.C.C. Wire has maintained its supremacy. During that period it has been continuously produced according to the same methods in millions of pounds yearly for the most exacting buyers of wire products for electrical uses.

Colonial Copper Clad Wire has been produced continuously for a longer period and in larger quantities than the combined quantities and periods of manufacture of all other past or present competitive products. It has stood the acid test of time in service tests and unbroken continuity of manufacture as no other wire has done.

It is probably not overstating the case to say that Colonial Copper Clad Wire is the only copper clad wire that has been produced in which a thorough weld is secured between the copper and the steel—a weld made by pressure between two accurately centralized, previously treated and prepared plastic metals, on exactly the same principle that the blacksmith welds his two pieces of iron into a single piece of equal or greater strength than the original bars. The most exacting tests of twisting, pulling, hammering, heating, and quenching, immersion in acids, etc., fail to indicate that the union between copper and steel in Colonial Copper Clad Wire is not of a strength substantially equal to the strength of the copper itself. A weld of this sort must not be confused with a union where the metals are merely melted together.

Do not be misled, but write for Bulletin No. 202 for further information about C.C.C. Wire.

Telephone Insulator

Trade Mark

Registered

Height 2½ inches, diameter 1½ inches
with two ¼ inch wire grooves.

The galvanized lag screw, which is securely cemented into the insulator, is flattened just below the insulator for engaging a wrench.

Especially adapted for use in mines, and for rural lines, general service lines etc.

ESTABLISHED 1849
BRADSTREET'S

Offices Throughout the Civilized
World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

THE Amelite

Eliminating the Difficulties of Efficient Store Lighting

Brilliant, thoroughly diffused light, a fixture that is handsome yet moderate in cost, you get these in the AMELITE—a real achievement in store lighting efficiency.

It gives you all the advantages, and none of the disadvantages, of the separate bowl and reflector. One piece, no connections; readily installed. The prismatic crystal band, which diffuses the light, is a feature alone sufficient to make the AMELITE a noteworthy success.

For you the AMELITE means sales—quick, sure and certain. Its established demand assures a ready market for you.

Write for Prices Today

Consolidated Lamp and Glass Company
CORAOPOLIS, PA.

WM. P. GARVIN, Canadian Representative,
62 King Street East, HAMILTON, ONTARIO

The AMELITE is made in three sizes, furnished with or without fixture.
For the extra large room use the 14 in. AMELITE.

Electrical Switch Boxes

— of the Finest Construction —

Form Steel Boxes, Motor Starting Switches, (steel enclosed), Motor Drip Pans, Motor Covers, Rheostat Boxes and Accessories.

Constructed to give the best service and made according to the best principles of workmanship in every detail.

Illustration shows our new Service Box No. 1005, 30 Amp., 125 Volt, double pole, size 8" long x 5½" wide x 2½" deep. It has a carrying capacity up to standard and is approved by Hydro Electric Commission. High grade material and the best of workmanship, make this box the most reliable on the market, and no other box can be installed so quickly.

We carry a complete line from 30 amp. 125 volt up to and including 1200 amp. 600 volt, and we always have on hand from 4000 to 5000 type E Boxes ready for delivery.

Why not get our prices. You will find them reasonable. Our aim is reliability and value with every order.

THE NEW COMPETITION

An examination of the conditions underlying the radical change that is taking place in the commercial and industrial world—the change from a competitive to a co-operative basis.

By Arthur Jerome Eddy, Author of "The Law of Combinations" etc.

Mr. Eddy believes that a radical change is taking place in the commercial and industrial world. He preaches the same doctrine as Mr. W. L. Goodwin, the get-together doctrine. He believes that competition, as it is generally practiced, is costly in operation, and he offers some very practical and concrete suggestions, including the "open price" policy, about which we are hearing so much and which promises solution of some, at least, of the ills in our industrial life.

Mr. Eddy's book is for the man, no matter what his business in life, who has a competitor—and that includes most of us. It opens to view a "land of promise" where everybody gets a square deal and everybody knows he gets it. No man can read this book without, in some measure, having his business policy affected thereby.

Sixth revised edition, including the full texts of the Clayton and the Federal Trade Commission Laws, all important provisions of which are explained, defined and commented upon. 423 pages, including index; price \$1.60 postpaid from the

BUYERS AND SELLERS OF
NEW AND USED MACHINERY

A Continent-wide Service

Resurface Commutators While in Service

The Ideal Resurfacer will keep your commutators in perfect condition. You can forever eliminate the trouble and expense of shutting down equipment to turn down commutators on a lathe. They can be kept in perfect condition by the occasional use of the Ideal Resurfacer while running under full load.

IDEAL COMMUTATOR RESURFACER

is a manufactured abrasive block that will quickly cut down high mica ridges and high bars, smooth out grooves and low spots on your commutators. It is non-metallic and non-copper collecting. Not a natural stone, sometimes hard and sometimes soft, that clogs with copper dust, but a specially prepared product of uniform density and cutting quality throughout.

FOR "D-C" OR "A-C" EQUIPMENT

The Ideal is equally effective on both "D-C" and "A-C" equipment—it will keep commutators and collector rings smooth, free from sparking and save in wear and tear upon carbon brushes. It will pay for itself many times through increased efficiency of your equipment and in time and labor saved, keeping commutators and collector rings in A-1 condition.

SEND THE COUPON

In order that you may convince yourself of the value of the Ideal we want you to try it out on your own equipment. If you like it send us a check—if not return it at our expense—the trial will not have cost you a cent. That is fair—fill out the coupon now while the matter is in mind.

Westinghouse Induction Feeder Regulators

Quick-acting magnetic brake enables very close regulation of feeder voltage.

Rugged operating motor designed for high starting torque with small current.

Enclosed gear and pinion, and protected hand wheel.

Worm mechanism with end-thrust ball bearing reduces friction, giving smooth operation.

Heavy steel shaft and perfect alignment, give uniform air gap and prevent vibration.

Form-wound impregnated rotor coils, held in open slots by fibre wedges, facilitate repairs if needed.

Heavy steel rings, carefully insulated and assembled over form-wound secondary coils, prevent insulation troubles from coil distortion due to short circuits or current surges in feeder circuit.

Secondary relay, with self-contained limit switch, permanently mounted on top cover, wired to motor, and provided with terminals for control circuit, reduces cost of installation and eliminates any chances of failure of operation due to faulty control wiring.

Top cover with long bearing bushing, bolted to bearing bracket.

Top bearing bracket bolted to end plate easy to remove.

Laminated-steel frameless core, assembled by hand and clamped between steel endplates by through rivets permits of most efficient cooling action of insulating oil and reduces weight.

Heavy cast bearing bracket, with bearing bushing, helps eliminate vibration.

Single-phase Regulator with Tank Removed
(Note Complete Accessibility)

Above are given some of the reasons for the unrivalled service record of the Westinghouse Type "C" Induction Feeder Regulators. Note particularly the rugged mechanical construction, the heavy bracing of the stator coils, and the unique core construction giving free oil circulation.

For more information write for leaflets 3916 and 3937.

This **SOLENOID SWITCH** has been adopted
by the Hydro Electric Commission

They use it for
STREET LIGHTING

Now the fact that it is used by the Hydro-Electric Commission is proof that it is all we claim for it. It certainly is not an experiment. by the fact that it is giving efficient service in many towns throughout Ontario, as well as the other provinces.

No springs, swivels or other complicated mechanisms to give trouble. They close magnetically and are opened by gravity assisted by the tension of the laminated copper contact. All arcing is taken up on the carbons.

Increase the efficiency of your system and decrease the cost of installation by using our Type 17 H.E.P. Solenoid Switches, which are suitable for any frequency on multiple circuit or D.C. Series circuit.

Adjusto-Lite
A FARBERWARE PRODUCT
TRADE MARK
FARBERWARE - BROOKLYN

It Clamps Everywhere

Patented in U. S. and Canada

Every Home, Office and Store In Your Town Needs Adjusto-Lite

And you can sell them Adjusto-Lite. Because it fills the need for a strong clear light in many places where the regular lighting is insufficient.

Simply show your customers how Adjusto-Lite clamps everywhere—to desk, shelf, counter, bed, mirror, etc. How it throws a clear pleasant light just where light is needed—and they will buy Adjusto-Lite because they need it, and will pay the reasonable price.

Many of our customers will come to you for Adjusto-Lite because they read about it in the Literary Digest, and other big publications which carry our strong advertising.

Send for our assortment of six lamps. Display them in use on desk or table. They'll sell! It is a quality product for quantity selling. No breakages—no trouble. Every lamp guaranteed by the House of Farberware.

**Adjusto-Lite Carries a Good
Profit for You—40 per cent.**

And it is a quality product through and through. Made in solid brass, statuary bronze or nickel. Finely finished. Compact, weighs little, easily carried about. Sold complete with 8-foot of silk cord and Bryant push-button socket. Guaranteed five years. Individually packed in display cartons for easy selling.

PRICES TO DEALERS

Brush Brass Finish, \$3.00

Statuary Bronze or Nickel, \$3.25

"National Protection"

RUST PROOF—ACID PROOF

A SHERARDIZED surface absolutely protects against rust. By the sherardizing process, the zinc is not merely applied as an enamel to the surface, but is *alloyed with the steel* and becomes a part of it. And more than that, the interior surface is given the same superior zinc protective treatment as the exterior.

A clear acid and alkali proof enamel is then baked on the Sherarduct and affords the best protection to the underlying surfaces against the destructive action of gases and acids. This enamel coating is also applied to the interior surface.

Both surfaces of Sherarduct are sherardized and enameled. "National" Protection is Double Protection. Write for Descriptive Bulletin No. 50.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance.
Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is \$86.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 580 describes this instrument.

PRODUCTS

Quality First

O-B Trolley Retrievers and Catchers

For the Good of the—

Overhead

Even if a "wild" pole does not pull down a span or two, it strains the line and loosens things generally.

O-B Retriever (for high speed) catches the pole and pulls it down below the span. O-B Catcher (for city service) catches the pole and permits no "stepping-up."

SHOP

Few, sturdy parts—simple, rugged mechanism keeps O-B Retrievers and Catchers out of the shop and on duty. If repairs are necessary the parts are perfectly interchangeable in each device.

Trainmen

O-B Catchers and Retrievers are always ready. They relieve your conductors. Only one way to set O-B Catchers and Retrievers and that way is easy.

Try them on your road at our expense

Monarch Electric Co., Limited

District Montreal

St. Lambert, P.Q.

From Source to Service

—from generation of power to ultimate use, the electrical equipment that the dealer offers his customers should be backed by quality, workmanship and reputation. The good work of the motor can only be realized by the good service of the lamp.

Edison Mazda Tungsten Lamps

have a Dominion-wide reputation for excellence of production. Correct in every detail of design and manufacture they insure economical use of current, retain a uniform brightness and yield long service.

The dealer who stocks the EDISON MAZDA TUNGSTEN LAMPS has the satisfaction of selling an article produced by skilled Canadian workmen and a lamp that is capable of attracting a big volume of the most profitable custom to his store.

Let us co-operate with you in obtaining the maximum of lamp sales in your district. Write us to-day.

For Security

MORE valuable by far than the actual protection of your property, is the peace of mind the fire department gives you. It is for the same reason, as much as for their greater intrinsic worth, that "FRANKLIN" devices are so desirable in your plant.

You can bank on them. "Install the 'FRANKLIN' and Forget It," is more than an advertising catch-line. You actually can and will forget your equipment—stop worrying about it—wherever "FRANKLIN" devices are installed.

The "FRANKLIN" Disconnecting Switch, equipped with the "Franklin" Positive Lock, cannot be forced open by electrical expulsion strains; the closed bridge above the switch-blade, formed by the locking jaws, prevents. These jaws can swing open only in a direction opposite to that of the resultant electrical force. Yet, by the rotating action of the cams on the pull-ring against the lugs on the lock-posts, a single easy pull with any hook swings open the jaws and withdraws the blade.

Other well-known "FRANKLIN" products are Post-Type Insulators, Potheads, Doors for Bus and Switch Compartments, Instrument Cutout Switches, Cleat Type Insulators, Air Pressure Relays, etc., and the new "FRANKLIN" Fuse. Write for descriptive Bulletins.

Universal Insulator Supports

SAVE
Time, Labor and Material

UNIVERSAL INSULATOR SUPPORTS are specially designed malleable iron clamps made in four sizes for securing Insulators to open steel framework for wiring mills, foundries, shops, bridges, piers, elevated railways, subways, train sheds—and similar structures. They are easily attached, and by their use, electric wiring for lights, motors, generators, cranes, etc., can be installed with a great saving of labor and material.

5000 Ampere, 7500 Volt Indoor Type Disconnecting Switch

"Three E" Disconnecting Switches

are made for both indoor and outdoor service, for voltages 750 to 110,000, and for various ampere capacities.

Our patented construction gives them the following advantages:—

Self Alignment

Perfect Contacting

Cool Operation (even at overloads)

Engineers, Construction Men and Operators should know more about them. Our new literature tells the story. Send for it today.

They are supplied with or without locking device.

THE SCOOP CONVEYOR

*The Scoop Conveyor
Keeps Equipment Moving*

*Two or More Scoop Conveyors
Make a Flexible Arrangement*

*Unloading Hopper Bottom Cars Direct
Into Trucks with a Scoop Conveyor*

*Sand, Gravel, Coal, etc., Easily
Loaded with a Scoop Conveyor*

**Does the work of from
6 to 12 men**

in loading coal, coke, ashes, sand, gravel, dirt, crushed stone, etc., into trucks or cars or transferring it from one place to another.

Used in connection with handling coal or ashes around the power plant or for digging ditches or building roads, it is one of the greatest labor and time savers. It keeps equipment moving. Enables men to work faster and easier. Eliminates much shovel and wheelbarrow work. Does three to five days' work in one.

OVER 1000 USERS

The Scoop Conveyor has been adopted by over 1,000 leading contractors, manufacturers and coal dealers because it is durable, light, compact, easily moved around and low in cost. About one-half of our sales are "repeat orders."

It is called "Scoop Conveyor" because the carrying belt receives its load over a scoop which can be pushed or completely buried into the material to be conveyed. This permits of scraping the material onto the carrying belt instead of lifting it by shovelfuls into the receiving hoppers fitted to ordinary portable belt conveyors and results in a saving of fifty per cent. of the labor in feeding.

Robbins & Myers New Power Stand General Utility Motor

This new motor is especially suited for driving the many small power machines about the farm and country home. It is portable so it can be carried easily from place to place and connected up to the washing machine, churn, cream separator, grindstone, ice cream freezer or any of the other small power machines which can be equipped with a pulley.

The outfit consists of a $\frac{1}{4}$ H. P. motor with a spiral type back gear which reduces the motor speed of 1150 r.p.m. to a speed of 285 r.p.m. at the pulley. The gears are fully enclosed and packed with grease.

A three-step pulley is supplied which consists of groove pulleys of 4 inches and 3 $\frac{5}{16}$ inches diameter for $\frac{5}{16}$ -inch round belt and a crown pulley of 2 $\frac{1}{2}$ -inch diameter and 2-inch face for flat belt.

The motor is mounted on an iron tripod base with rubber caps on the feet. A brace rod with a clamp for attachment to the driven machine is provided to maintain the belt tension. The rod is telescopic for adjustment of length and the clamp can be turned at any angle. Cord and plug are supplied with the outfit.

The motor is furnished for operation on 32-volt private lighting plant circuits and for 110-volt, 60 cycle A. C. circuits.

No. 12

Placing Returned Technical Men

From time to time we have spoken of the technical clearing houses recently established by the Dominion Government in Toronto and elsewhere and we have ample evidence that the success attending the plan has fully justified those who originally suggested it. That does not mean, however, that all returned technical men are being placed as rapidly as they register and we are advised that at the moment there is a considerably greater supply of technical ability than the demand is absorbing. Employers who can make use of trained men in their business are therefore again urged to consider whether they cannot place one or more of these men at once so that the process of absorption may go on steadily.

It might not be out of place to offer just one little word by way of suggestion to those returned men themselves who appear to have difficulty in securing suitable positions. It is quite true that Canada is in duty bound to see that these men are placed in positions where they can do useful work and live satisfactory lives. On the other hand they must not forget that they are more or less out of touch with civilian and industrial life and must not expect individual employers to place unlimited confidence in their ability until they have to some extent at least, proven themselves. It is entirely reasonable that many of the men that have been overseas for two or three or four years, and have had a wide experience, will very quickly develop into valuable assets to any business, and command good salaries. In the meantime, however, and during the period of trying out, is it not reason-

able to expect that returned technical men now, just as men had to do before the war, should be satisfied to start in somewhere nearer the bottom of the ladder. The difference will lie in the fact that their training and experience will advance them more rapidly; also in the fact that employers will show every possible consideration to the man who has been overseas.

Canadian Institute of Electrical Engineers

The argument has been advanced by an opponent of the plan of a Canadian Institute of Electrical Engineers that while it is true electrical engineers have many independent interests still there is much in common among all engineers and it is necessary that the whole technical field should show a united front if the general ills of the engineering profession are to be remedied. We believe that is the right idea, entirely—a united front. Let us remember, however, that the work of General Foch in France was no less effective because his armies were not all of one nationality. His success lay in getting these armies to work in synchronism, not in forming them into one great big chaotic mass.

The fault with the E. I. C. organization idea is that it embodies the "mass formation" idea. On the other hand, and as a substitute for this, the Canadian Institute of Electrical Engineers, the Mining Institute, the Society of Mechanical Engineers, etc., propose independence of action except in matters of general interest, which matters may be handled by a common council composed of representatives of all the engineering sections.

What stronger combination of forces could one wish than an engineering council composed of representatives elected by each of several national organizations. It is the modern method of organization—just as applicable in this case as in the management of any business large enough to subdivide into departments. And unless the engineering organizations are operated on a business basis there is little chance that the status of the engineer will be much different ten years hence from what it is to-day.

Closer Co-operation

Evidence that at least two of the sections of the electrical industry are getting into closer working relationship is given by the appointment just announced, of a common secretary to the two organizations—the Canadian Associated Manufacturers of Electrical Supplies and the Canadian Electrical Jobbers' Association. This is a step in the right direction but only the first step. The fact we have all got to come to a realization of is that the success of our industry lies in the development of the field that consumes electrical devices and electrical current. The demand for both must be many times increased. Since these items are interdependent, it follows that much good could result from a closer relationship between the manufacturers, jobbers, engineers and central stations; and since, further, the throat of the funnel, so to speak, through which electrical appliances flow to the public is the contractor-dealer, it also follows that he must be drawn closer into the family circle.

Mr. Andrew, the new secretary, is very favorably known to every one of the sections of the industry mentioned above and is, therefore, in a splendid position to take advantage of what appears to us to be a most timely opportunity to get all the wheels moving in the same direction. It isn't an easy task, or one that can be accomplished in a day, but we believe it is possible. We also have such confidence in Mr. Andrew as to believe that if he makes this his aim he will accomplish his purpose. The entire industry humming in synchronism should be the goal towards which we are all striving.

Two Big Electrical Conventions

Canadian Electrical Association — Alexandria Bay, June 27th and 28th

The annual convention of the Canadian Electrical Association will be held this year on June 27-28. The meeting place is Alexandria Bay, Thousand Islands, so that the members will be able to combine a delightful outing with two days profitable business.

The program will consist largely of presentation of reports of committees which have been such a valuable feature in past years. The following committees will report: Overhead Lines Committee; Commercial Light and Power Sales; Rate Research; Prime movers; Electrical Apparatus. Two or three special papers will also be presented, one of which, by Mr. Ernest P. Fredericks, will deal with the "Service at Cost" question.

The boat will leave Toronto on Wednesday afternoon at 3.30, and Montreal Wednesday afternoon at 1.00; return on Sunday. Special rates to convention delegates have been arranged. Further particulars may be obtained from the secretary, Mr. Wm. Volkman, Toronto Electric Light Company, 10 Adelaide Street East, Toronto.

Mr. A. Monro Grier, K.C., President
Canadian Electrical Association

Mr. O. H. Scott, President Association of
Municipal Electrical Engineers

Association of Municipal Electrical Engineers — Niagara Falls, June 19th, 20th and 21st

The programs have been distributed for the semi-annual convention of the Association of Municipal Electrical Engineers which will be held at the Clifton Hotel, Niagara Falls, Ont., on June 19, 20 and 21. The program includes two interesting papers: "Routine Handling of Customers' Accounts," by R. C. McCollum and "Overhead Distribution Systems," by C. E. Schwenger. A. Monro Grier, K.C., will be the speaker at the convention dinner on Thursday evening and W. L. Goodwin and Samuel A. Chase will occupy the morning session on Friday. Saturday morning will be given over to an inspection trip of the Chippewa Development work which is steadily going forward.

A number of amendments to the Constitution and By-laws of the association will be considered, one of which provides for a change of name to the "Association of Municipal Electrical Utilities."

Further information may be obtained from the secretary of the association, Mr. S. R. A. Clement, Ontario Hydro offices, University Avenue, Toronto.

Steam-Electric Plant of the Dominion Power and Transmission Company, Hamilton

III.—Electrical Generators and Auxiliary Equipment

Alternating Current Turbo-generator

The turbines, described in our last issue, drive 12,500 kv.a. Westinghouse generators, 6,600 volts, 3 phase, 66 2/3 cycle, 4 poles, 2,000 r.p.m.

The generators are revolving field type, direct connected to steam turbine, with end bells removable to allow access to windings. Field coils are wound with copper strap in slots cut in field core; insulating material subject to temperature of 150 deg. C. without injury. Armature core is built of laminated steel, in cast iron frame and held firmly in place between two end plates. The winding is insulated with material subject to temperature of 90 deg. C. without injury.

The generators are cooled and air treated by special generator humidifiers, two humidifiers to each three generators. Humidifiers were built to the following specifications by the Carrier Air Conditioning Company.

Cross section of casings 13 ft. 8 in. in width, 13 ft. 1 1/2 in. high and 10 ft. 0 in. in length, casing of No. 18 gauge galvanized iron, braced with 1 1/2 x 1 1/2 angles. Inspection door is in side of humidifier for inspection and cleaning, with glass panels. Settling tanks 18 in. high of No. 16 gauge galvanized iron, braced with 1 1/2 x 1 1/2 in. angles. Suction strainer

Portion 6600 volt switch room

in one end of each tank of 20 mesh copper wire cloth; top of suction chamber covered with galvanized iron door to keep out dirt; strainer prevents dirt and foreign matter getting into spray nozzles. Spray nozzles give finely atomized spray completely filling spray chamber; are of brass, set so as to discharge against direction of flow of air, and placed 3 ft. in front of eliminator plates. The eliminators are vertical galvanized iron plates with parallel surfaces, spaced uniformly in rows, and bent to small angle so that adjacent plates form continuous sinuous passageway through

which air passes; plates are mounted on galvanized angle iron framework, supported from bottom of settling tank; joint between eliminator frame and spray chamber is water tight. Pumps are centrifugal with direct motor drive.

The first four corrugations of the eliminator plates act as a washing surface. These eliminators are spaced so that air is broken up into small, thin layers, making all particles of dust come in contact with wet surface of eliminators. Special means is provided by an independent set of flooding

West side 6600 volt bus structure

nozzles for maintaining a constant sheet of water flowing down the wet surfaces continually; a valve is provided for closing off the spray nozzles in very humid weather and washing, procured by flooded eliminators.

Each washer includes the following: number of spray nozzles, 560; number of flooding nozzles, 54; spacing of eliminators, 1 1/2 in.; area suction strainer per ft. width, 1 sq. ft.; gals. water per minute, 367; size of motor, (3 phase, 550 v. 66-2/3 cy.) 15 h.p.; velocity of air through washer per minute, 500 ft.; normal cap. of each washer per minute, 78,000 cu. ft.; overload cap. of each washer per min. 109,000 cu. ft.; washing surface exclusive of eliminator surface, 1,440 sq. ft.

Each washer is provided with marine light with switch outside.

The current from the generators is carried by twelve 500,000 c.m. lead covered cables to the controlling breakers in the switch room. Each generator is separately excited by a motor driven exciter.

The normal full rating of each exciter generator based on the specified full load voltage is 75 k.w., 125 volts, 600 amps. full load, 4 poles, 1280 r.p.m.; shunt interpolar winding. The generator is driven by a Canadian Westinghouse induction motor, 112 h.p., 550 volts, 3 phase, 6 poles, 1333 r.p.m. at no load; 1280 r.p.m. full load.

A steam driven exciter is also available for either machine in case of necessity.

The turbine is horizontal type impulse adapted for driv-

ing a 75 kw., d.c. generator. Gauge pressure at throttle is 200 lbs. superheated steam; back pressure of 0 lbs. vacuum in exhaust pipe referred to bar. pres. of 30 in. Superheated at throttle 160 deg. F. r.p.m. 2750. The turbine blades are made of nickel iron.

The current, generated at 6600 volts, is transformed to 42,000 volts by three 4,000 kv.a. transformers, delta connected to each machine.

The normal full load rating of these transformers is based on the following specified phase, cycles and voltages: 4000 kv.a., shell type, single phase, 66.6 cy., 41,000/13,200/6,600 volts. The transformers are designed for operation in oil; the cooling is effected by means of water circulated through cooling coils placed beneath surface of oil.

Windings are of shell type, both high and low tension divided into many flat coils and the layers separated from each other by insulating sleeves covering the conductors. The coils are individually insulated and assembled into groups with strong insulating barriers between them.

The machines, together with the transformers, are considered a unit and are tied together only on the 42,000 volt side, thus introducing two banks of transformers between machines in the event of trouble in one of them. Two transmission lines pass through the roof of the building and carry the output to the switching station (outdoor type at Bartonville.)

All electrical apparatus is remote controlled from the operating room.

The plant is housed in a modern brick and steel fire-proof building of pleasing appearance; the building is equipped with every convenience for the operating staff. The

brick, concrete floors and buff gypsum roof. The steel throughout is painted grey and the combination presents a neat and business-like appearance.

The larger rooms are effectively illuminated by nitrogen lamps properly contained, hung from the roof trusses.

The 50-ton power-house crane (Cleveland Crane & Engine Co.) is also electrically operated. The maximum working

Operating and control room

load of the main hoist is 50 net tons and of the auxiliary hoist 5 net tons. Each hoist will carry 25 per cent. overload. From centre to centre of runway rails is 53 ft. 4 in. Maximum lift of hook is: main 40 ft. 0 in., aux. 50 ft. 0 in.

Speeds are as follows:

	Full load	No load.
Main hoist	5 f.p.m.	10 f.p.m.
Aux.	20 f.p.m.	40 f.p.m.
Bridge travel	150 f.p.m.	200 f.p.m.
Trolley	75 f.p.m.	100 f.p.m.

Motors are Westinghouse, 125 volts, of following sizes: main hoist, 25 h.p.; auxiliary, 10 h.p.; bridge travel, 25 h.p.; trolley, 10 h.p.

The brakes are foot operated from cage with mechanical brakes of double friction, band type self-lubricating running submerged in oil. Each hoist has automatic electric brake of post type attached to armature shaft of hoist motor and operated by a solenoid; is connected to apply itself on failure of

42,000 volt switch and bus room

engine room is finished in white enamel, satin brick walls, buff gypsum ceiling and red quarry tile floor, and is served by an electric crane. The remainder of the plant, excepting the office and control room is finished with red pressed

Transformer pockets

current. It is equally effective in stopping motor when hoisting or lowering, and is capable of sustaining full load of hoist.

Each hoist is provided with auto circuit breaker that breaks circuit when hook is raised above or descends below, predetermined point; is of cage operated type. The hoisting rope is of special crucible steel 6 x 37 construction. Trolley is 3/0 bars.

From the switching station a single 45,000 volt circuit passes out to Burlington, a double circuit to Brantford, three circuits to Power Glen (near St. Catharines) and two circuits to a number of transforming stations which serve the industrial needs of the city of Hamilton. (Power Glen, it will be remembered, is the location of the De Cew Falls hydro-electric development of the company which is tied in with the steam plant.) 13,000 volt lines also supply power to Welland, Port Colborne, Thorold, St. Catharines, Beamsville, Grimsby, Oakville, Dundas and other towns in the district.

The electric railway system of the company which has its centre at the Terminal Building, Hamilton, where the offices of the company are located, gives an excellent interurban service to Brantford, Dundas, Oakville and Beamsville, in addition to the local system.

The steam electric plant, the complete description of which is completed in this, the third article of the series, was designed and built by the company's own organization. Mr. W. C. Hawkins is managing director and Mr. E. P. Coleman, general manager; Mr. W. G. Angus, superintendent of operation; Mr. Waller, superintendent of railways; Mr. L. W. Pratt, manager of light and power sales; Mr. George Service is mechanical engineer at the plant and Mr. Chas. H. Hutton, electrical engineer in charge of operation.

American Engineering Standards Committee

In many lines of engineering much excellent standardization work had been done before the war; the war emphasized its importance and showed most clearly the need of co-operation to prevent the confusion caused by the promulgation of overlapping standards by independent bodies. During the war the Government departments co-ordinated these efforts in certain lines and greatly assisted in unifying them. The American Engineering Standards Committee representing the American Institute of Electrical Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Civil Engineers, American Society of Mechanical Engineers, and American Society for Testing Materials, together with representatives of the U. S. Government Departments of War, Navy and Commerce, has just completed and adopted a revision of its constitution which has been sent to the Governing Boards of all the departments and societies represented on the committee with a request for its ratification. The new constitution changes the name to American Engineering Standards Association, the change from "Committee" to "Association" more fittingly indicating the wide scope of the interests involved.

The objects of the Association are stated as follows:

1. To unify and simplify the methods of arriving at engineering standards, to secure co-operation between various organizations and to prevent duplication of standardization work;
2. To promulgate rules for the development and adoption of standards;
3. To revise and pass upon recommendations for standards submitted as provided in the Rules of Procedure, but not to initiate, define or develop the details of any particular standard;
5. To give an international status to approved American engineering standards;

6. To co-operate with similar organizations in other countries and to promote international standardization.

Means are provided for increasing the number of representatives in the Association by invitation or on request. Several important organizations interested in standardization will be invited to appoint representatives as soon as the necessary power is obtained.

New Rail Route to Western Canada

Travellers between Eastern and Western Canada are showing their appreciation of the high standard of railway service afforded by "The National," the splendid train which operates between Toronto and Winnipeg. "The National" uses the rails of the Grand Trunk to North Bay, the Temiskaming and Northern Ontario (Provincial Government Line) to Cochrane, and the Canadian National Railways to Winnipeg, where it links up with the Grand Trunk Pacific for all important points in Western Canada. A pleasant run to Toronto by the Grand Trunk and "The National" is ready to carry you westward. The departure of "The National" from Toronto is at 9.15 p.m. on Tuesdays, Thursdays and Saturdays. North Bay is reached early next morning and there opens up for your admiration all the lakeland beauties of the territory served by the T. & N. O. Line, while the rich Cobalt and Porcupine districts may be inspected. These are followed by a wonderfully interesting trip through the sparsely populated territory of New Ontario, giving the traveller an opportunity of inspecting this fertile region, including the famed "clay belt," where tens of thousands of settlers will make their homes in the future. The area of New Ontario is 330,000 square miles, fully four times the size of Old Ontario, and in addition to great expanses of good farming land, it has wonderful resources in timber, minerals, water power, fish and game.

The three railways have combined to make the through passenger service over this new route the equal of that offered anywhere on the continent. The smooth, straight and level roadbed embodies all that has been learned in three-quarters of a century of railroad building. The greatest travel comfort is assured. The use of the new route involves no extra fare, as compared with any other route available, between points in Eastern and Western Canada.

It is stated that the Ontario Hydro-electric Power Commission have purchased from James Battle his electrical plant and transformer equipment at Thorold for \$100,000. Mr. Battle held a 26 year contract with the Ontario Power Company and supplied a number of industries and private consumers in and around Thorold.

The Administrative Commissioners of Montreal have renewed, for a period of ten years, the franchise of the Southern Counties Railway. The city will get an increased price for the privilege, at the rate of \$1,400 per mile per annum, while the company will also have to bear the cost of removing snow, cleaning and repairing the streets, this being estimated at \$4,167. The company further agrees to construct underground conduits for its power conductors, if required to do so.

The Toronto Hydro Electric System have distributed their annual report for the year ending December 31, 1918. The net income from operations was \$21,667, and the balance carried forward to 1919 is \$63,970. The report of the general manager, H. H. Couzens, states that in spite of the discontinuance of the demand for munitions and war supplies, which brought the load on the Toronto System up to approximately 50,000 h.p., the present peak demand is within 3,000 or 4,000 kw. of the demand at the corresponding period a year ago.

Comparison of Central Electric Station Industry in Canada and United States, 1917*

From our Ottawa Correspondent

The results of the census of central electric stations taken in the United States for the year 1917 have just been made public, and it is interesting to compare them with the results of the similar census taken in Canada for the same period, and made public some months ago.

In both countries the basis of compilation has been the same. Stations engaged in the sale of electrical energy for light and power are classed as central stations and include both generating and non-generating establishments. Establishments generating electrical energy for their own use not included. As the basis of compilation is similar, the tabulated results may be satisfactorily compared. The comparison in the attached table is based on total and per capita figures. As central station industry is, from its nature, very closely associated with the general public, the per capita figures form a logical and reasonable basis for comparison.

In respect to the total number of stations, it will be noted that Canada has 666, compared with 6,541 in the United States, or 0.080 per thousand population in Canada compared with 0.063 per thousand population in the United States. The proportion of commercial stations is about the same in both countries, while for municipal stations, Canada has the advantage of 0.041 as against 0.022 in the United States.

Referring to the primary power, Canada has a total installed horse power in central stations of 1,844,571 h.p., as against 12,857,998 total horse power installed in the United States, or 221.0 h.p. per thousand population in Canada, as against 124.0 per thousand population in the United States. The analysis of the primary power installation forms, however, the most interesting feature of comparison. Steam power in Canadian stations totals 180,200 h.p., while in the United States it totals 8,389,389 h.p., or on a per capita basis, 21.6 h.p. for Canada, as against 81.0 for the United States. On the other hand, the water-driven installation of

central stations in Canada is 1,652,661 h.p., as against 4,251,423 h.p. for the United States, or on a per capita basis 198 h.p. for Canada, compared with 41 for the United States. In other words, 90 per cent. of the central station installation in Canada is based upon water power, while only 33 per cent. is so based in the United States.

The advantage possessed by hydro power as the basic power for central station work is strikingly shown by an analysis of the figures in the attached table. The number of persons employed in the central station industry per thousand and horse power installed is 4.8 in Canada, as against 8.2 in the United States, or in other words, the average installation in horse power per employee is 2,084 h.p. in Canada, as against 1,217 h.p. in the United States, indicating the lower staff operating costs in hydro stations. The salaries and wages per horse power installed per annum total \$4.22 in Canada as against \$7.47 in the United States.

While it is possible to compare the income from electrical service in the two countries, the records of the total expenses, exclusive of the salaries and wages, are not available in the Canadian census. It will be noted, however, that while the total income for electric service per capita in Canada is greater than in the United States, it is only \$24.14 per horse power installed in Canada, as against \$39.05 per horse power installed in the United States. After deducting the salaries and wages, the central stations receive a net income of \$19.92 in Canada and \$31.58 in the United States (both figures based on primary installation), to provide for the fixed and operating charges apart from staff. Looking at it from the standpoint of the public, it would appear that the power and light users of Canada, after providing for the staff operating charges, are taxed for the remaining annual charges only \$19.92, as compared with \$31.58 in the United States, on the basis of service rendered, or at least on the basis of primary power installation available for service. Undoubtedly the fuel costs arising from the greater proportion of the fuel driven stations in the United States as compared with the greater proportion of water-driven plants in Canada account largely for these figures.

A further interesting fact in connection with the installation is the size of the primary units in the two countries. In the steam plants the average per unit in Canada is 718 h.p.,

*Based on a census of central electric stations taken in Canada by the Dominion Bureau of Statistics in co-operation with the Dominion Water Power Branch, and in the United States by Bureau of Census, for the year 1917.

Comparison of Central Electric Station Industry in Canada and the United States, 1917

Item	Canada	Total	Per 1000 population	
			Canada	U.S.A.
Number of Stations	666.0	6,541.0	0.080	0.063
Commercial	323.0	4,224.0	0.039	0.041
Municipal	343.0	2,317.0	0.041	0.022
Income (from Electric Service)	\$44,536,848.00	\$502,100,408.00	\$5,338.00	\$4,851.00
Income (from Electric Service) per h.p. installed	\$24.14	\$39.05		
Number of Persons Employed	8,847.0	105,546.0	1.06	1.02
Number of Persons Employed per 1,000 h.p. installed	4.80	8.21		
Salaries and Wages (Totals)	\$7,777,715.00	\$95,239,954.00	\$932.00	\$920.00
Salaries and Wages per h.p. installed	\$4.22	\$7.47		
Installation:—				
Total Horse Power	1,844,571.0	12,857,998.0	221.0	124.0
Steam Engines, number	251.0	7,464.0	0.031	0.072
Horse Power (Total)	180,200.0	8,389,389.0	21.6	81.0
Horse Power (Average per Unit)	718.0	1,124.0		
Gas and Oil Engines, Number	113.0	2,946.0	0.013	0.028
Horse Power (Total)	11,710.0	217,186.0	1.4	2.1
Horse Power (Average per Unit)	104.0	74.0		
Water Wheels, Number	619.0	3,357.0	0.074	0.032
Horse Power (Total)	1,652,661.0	4,251,423.0	198.0	41.0
Horse Power (Average per Unit)	2,670.0	1,266.0		
Average Installation in h.p. per Employee	2,084.0	1,217.0		
Average Capacity of Stations in h.p.	2,770.0	1,965.0		

Table based on estimated population in 1917,—Canada 8,343,000; United States 103,500,000; and on census of Central Electric Stations industry taken in both countries in 1917.

as compared with 1,124 h.p. in the United States. In Canada the average water-wheel unit is 2,670 h.p., as compared with 1,266 h.p. in the States. These differences are logical considering the trend of the central station installation towards steam and water in the respective countries. The average capacity of the Canadian station is 2,770 h.p., as compared with 1,965 in the States. Other interesting ratios and comparisons may be drawn from the figures in the table.

It has been stated that Canada possesses a peculiar advantage in respect to its water power endowment in that practically every commercial and industrial centre is within easy transmission distance of and is already served with ample supplies of economically developed hydro-electric power. That this unique advantage has been appreciated in principle and is being realized in practice is strikingly shown by the above figures which indicate the extent to which the water resources of the Dominion are being adapted to the production of electrical energy, and the substantial benefits accruing to the public therefrom.

Power Factor Correction and Voltage Regulation

Obtained with Two Water Wheel Type Generators Used as Synchronous Condensers by the City of Sherbrooke Gas and Electricity Department

By C. J. Desbaillets*

Early in the year 1918 the corporation of Sherbrooke was asked for an additional thousand horsepower by the munition factories. It was impossible to deliver this power due to the fact that on both power houses of the corporation the load had a power factor of less than 60 per cent. On account of this very low power factor the generators were overloaded to the limit of their k.v.a. capacity although the actual load in kw. was considerably below what could be obtained from the turbines.

Following are the characteristics of the two plants of the corporation and their load carried early in the year nineteen hundred and eighteen:

*Manager and Engineer, Sherbrooke.

Rock Forest Plant

The Rock Forest plant is situated six miles from Sherbrooke. This plant consists of two 930 kw. generators connected to two 1,470 h.p. Morgan Smith turbines. The maximum load carried by this plant, previous to the change, was 1,700 kw. on the two machines, at a power-factor of sixty per cent. with an armature current of 124 amperes per machine, whereas the full load amperes at eighty-five per cent. power-factor was only ninety-seven.

The output of the turbines was thus only 2,260 h.p., and 420 h.p. were lost, as the two turbines were capable of delivering 2,680 electrical h.p. on the generator.

City Plant

This plant is located in the city of Sherbrooke, and consists of two 850 kw. generators at 85 per cent power-factor, connected to two 1,300 h.p. Boving wheels. The maximum load carried by this plant early in the year 1918 was 1,560 kw. on the two machines, with a power-factor of sixty per cent. and an armature current of 320 amperes, whereas the full load current was only 250 amperes. The output of the turbines was then only 2,150 h.p., and 450 h.p. were lost, as the two turbines were capable of delivering 2,600 h.p. to the generators.

It is evident, from the above figures, that the only remedy to the situation was the raising of the power-factor. The corporation had at its disposal two 625 kw. water wheel type generators, 225 r.p.m.; and it was decided to operate these generators as synchronous condensers.

After careful study, these machines were located in the distributing station, four thousand feet from the Frontenac Street power house, and they were started from rest by separating the feeder line from the Frontenac Street plant to the distributing station in two circuits; and thus, by using one generator of the Frontenac Street plant, the two synchronous motors were successfully started at the sub-station in the following manner.

One of the generators at the Frontenac Street plant is stopped, and full field of 250 amperes is applied; at the same time, at the end of the starting line at the distributing station, the synchronous motor switch is closed, and fifty amperes field current is applied. After signalling to the power house that everything is ready, the generator attendant slowly opens the gates of the turbine, and both machines are

Before and After—Showing the effect of the synchronous condensers on the voltage of the bus-bars

brought up to speed in synchronism. The generator in the Frontenac Street plant is synchronised to the bus with its synchronous condenser at the same time. The synchronous motor bus switch is then closed at the distributing station, thus connecting this synchronous motor on the sub-station bus bar, which is already in parallel with the Frontenac Street plant bus bar. The starting line is opened at the synchronous motor, and this machine is then floating on the bus bar of the distributing station.

The same performance applies to the starting of the second synchronous motor.

As you can see by the wiring diagram the starting line can be connected in parallel with the feeder line as soon as the two motors are started, and will make this line sufficient

Wiring diagram for synchronous motors

to carry the load of the two generators of the Frontenac Street plant.

It is to be noted that no additional copper was required for this starting line as when one of the generators is used to start the synchronous motor, the other machine can only deliver half of the plant capacity; therefore half the feeder line section is sufficient for the purpose.

The characteristics of these motors have been such that they have successfully kept in step in spite of various short circuits and grounds which have occurred during the year, and only one shut down was experienced during twelve months of operation.

Voltage Regulation

The Tirrill regulator which was used in connection with the generators had not given satisfaction, as the whole system was subject to heavy fluctuation due to a couple of steel furnaces operated by the Canadian Brakeshoe Company; and it was found almost impossible to keep the regulator in operation during the breaking of the charge on these steel furnaces.

This Tirrill regulator was then removed and installed in connection with the motor-generator set exciter at this distributing station and installing of the switching apparatus excitation for the synchronous motors.

Showing the two synchronous motors in operation

The series element of this regulator is connected to the steel furnace circuit, and the regulator is acting upon the synchronous motor exciter and is maintaining a constant voltage by varying the power-factor on the bus-bars. The two voltage charts will show what the voltage was before the change and after.

Horse Power Recovered

After the above mentioned change was made, the Frontenac Street power house was in position to deliver 1,940 kw. at eighty-eight per cent. power-factor with 300 amperes on the machine; and the Rock Forest plant has carried 2,120 kw. at ninety per cent. power-factor with 90 amperes per machine. This means that during nine months of the year 1918 the corporation was in position to sell a one thousand h.p. demand by the manufacturers of shells, without adding any machinery to their power houses, but simply by making use of two old generators, at an expense of approximately \$2,000 covering the removing of these machines to the distributing station and installing of the switching apparatus for the starting of same.

It may be interesting to know that prices were asked from the manufacturers to make these machines self-starting; this change would have cost in the neighborhood of \$7,000.00. Moreover, the starting of these machines, as described above, is done without any trouble or disturbance on the line.

Personal

Mr. S. L. B. Lines, manager Chamberlain & Hookham Meter Company, Toronto, has returned from a business trip to England.

Flight-Lieut. Rupert Davidson, of Cobourg, Ont., has accepted a position as electrical engineer on power development on the Para River, Brazil.

Mr. W. M. Andrew, of the Toronto office of the Canadian Westinghouse Company, has been appointed secretary of the recently formed associations of electrical manufacturers and electrical jobbers.

Mr. J. J. Ashworth, assistant general manager Canadian General Electric Company, has been elected a director of the company. **Mr. A. E. Dymont** has been elected vice president.

Electric Furnace for Melting Brass

There has been operating in the foundry of Messrs. Letson and Burpee, of Vancouver, for the past five months, the first electric furnace for melting brass ever installed in British Columbia. It is the invention of Mr. J. D. Shipton, a well-known electrical engineer in the terminal city, and has been eminently successful in its work. In an iron foundry where dirt and steam are everywhere, the simplicity of the furnace is what appeals to a foundry man. It is operated with the greatest facility and no real skill is required to

melted, showing practically no loss of zinc, only at the moment of pouring. Naturally some zinc is absorbed by the lining after the furnace has been re-lined, more especially if the lining has not been well burned before using. But this loss is very small. The design of the furnace is such that it will hold one thousand pounds of metal, which means that the hearth can hold about 1,400 lbs., still keeping the metal at a safe distance from the arc.

In charging, about 600 lbs. are put in the hearth by the feed door and 400 lbs. are put on the pre-heating shelf which is fed from the two openings in the top of the furnace. Those openings are then closed and the current switched on, and by the time the hearth portion has reached a temperature of about 1,500 degrees Fahr., that metal in the pre-heating chamber has reached a temperature of from 700 to

Electric smelting furnace for melting brass—Vancouver, B.C.

handle it. An ordinary workman can be taught in a few hours to look after it.

Its capacity is 500 lbs. in four hours from a cold furnace, and the consumption of electrical energy is 440 kw.h. to the ton; in a one-ton furnace it is 250 kw.h. The power-factor averages about 83 per cent., with good carbons. Consumption is about 10 lbs. to the ton. Its efficiency is shown up better on ten-hour service and on a 24-hour operation it is, naturally, still better. On account of its load-factor the cheapest possible rate can be secured from a power company for the current.

While this furnace is designed to melt 500 lbs. in four hours, it can be designed to melt this same charge in two hours. In fact there is practically no limit to the speed of melting, though at the same time it is not an advantage to so crowd the melting that the heat from the arcs cannot be absorbed by the metal fast enough without the upper portion nearest the arc is at a vaporizing temperature.

With this furnace, as high as 35 per cent. zinc has been

800 degrees Fahr. This is then dumped into the hearth and, in a few minutes, has reached its pouring temperature. Among foundry men there is no instance known where the pouring temperature has been greater than 1,650 degrees, and sometimes it is as low as 1,400 degrees Fahr.

It will be interesting to note the difference in these pouring temperatures and the temperatures mentioned in the pamphlet published by the United States Bureau of Mines last year. Mr. Shipton claims that it is not necessary to raise the temperature higher than the figure stated.

Eighty-five per cent. copper has been successfully melted and 15 per cent. zinc, and as low as 60 per cent. copper and 40 per cent. zinc, both ingot and scrap in all forms. The advantages of the pre-heater are greater efficiency, preservation of the top and no delays by having to add cold charges to the melted charge, thereby causing partial freezing which holds up the melting operation considerably.

In brief, the Shipton furnace has the following points which should appeal to everyone engaged in this class of

work—the hearth is rectangular in design and it is therefore a simple matter for a laborer in the foundry to re-line same; its choke coil regulator being of rugged construction, the only knowledge required to operate same is to turn a wheel one way or the other, thus regulating the voltage from 40 to 110; dust, dirt or steam does not prevent successful operation; no skilled labor is required to operate the furnace, the furnace tilts to pour its charge, this method having been found to give the most satisfaction in preference to tapping.

The only renewals needed each month is a cylindrical refractory sleeve used on the carbons where they enter the furnace walls, whose inner diameter corresponds with the diameter of the carbons used. One of the greatest advantages of the Shipton furnace is that it can be manufactured and sold for about one-half the price of any other electric brass melting furnace on the market.

Calculating the thermal efficiency of the one-ton furnace at 180 kw.h. as the theoretical heat required, or 154,800 calories, it will show a thermal efficiency of 72 per cent., which it must be admitted is very good indeed.

Electrical Equipment on the All-Metal Cars of the Manchester-Bury Electrical Section, Lancashire and Yorkshire Railway

By George Hughes, M. Inst. C. E.

When new motive power is required, the railway engineer has to consider the following points:—Geographical position, gradients, junctions, density of traffic, difficulties of operation, possible range of user, and future developments. The paper is arranged in the order as appertains in the passage of current:—

A shoe collects current from a side-contact live rail, the shoe pressure being 25 lbs. This shoe, fixed to the bogie, is connected to the trolley cables, from which connections are taken through the various parts of the equipment to the motors. A connection is taken to a rotary transformer, which supplies low-tension 100-volt current for operating the control equipment.

The trolley cables have been housed in Jarrah wood, as this material has been found the most satisfactory.

The electrical connecting of coaches is accomplished by "plug and socket" type couplers; the high tension (1,200-volt) is connected to the trolley cable, and the low tension (100-volt) to the rotary transformer; also a control coupler is connected to the multicore cable for the contactors.

The 1,200-volt portion of the equipment is placed in a high-tension compartment, completely isolated from the remainder of the car, the door of this compartment being interlocked with the main switch, which is of the single-blade type.

The rotary transformer is a 10-kilowatt machine; it has two windings on the armature, and is operated on the high-tension side by an automatic control-switch, which is necessary owing to the gaps in the live rail.

The electrical control equipment is of the shunt multiple-unit type, arranged for automatic or manual operation in the forward position, and manual only in the reverse. Field control is also provided for.

The automatic control is operated by means of relays governed by the main motor current. Succeeding contactors cannot operate until the motor current has fallen to a predetermined value, and the sequence of operation is controlled by electrical interlocks.

The controller has nine positions of the handle, the last being for supplementary field control, and there are four positions of the reversing handle.

The main circuit-breaker is of the magnetic shield type,

and can be tripped or re-set from the motorman's compartment.

The contactors are made up in two groups, one group at each end of the car, and controlling two motors. Each single contactor is fitted with a magnetic blow-out coil and two arcing horns protected by soapstone shields.

The motor cut-out is manually operated, and when in the normal position two motors are in circuit; if moved in either direction one or other of the motors is cut out.

Each reverser controls two motors, and is solenoid operated from the master controller.

In the motor-bogie the best locomotive practice has been adopted, and the design is the outcome of the development of the built-up frame bogie. The gear wheels are pressed on to the axle and bolted to the wheel centre. They are of mild steel, with involute teeth, No. 2 diametral pitch, and the load is taken uniformly on two teeth throughout the arc of action. The road wheels are of the standard locomotive-spoked type, and the tyres are made of Siemens-Martin steel of locomotive pattern but 5 inches wide, and are shrunk on to the wheel centres. The wheel centres are steel castings made by the Tropenas process. The bolster is of the box-girder form, with a lateral movement of $1\frac{1}{2}$ inch each way. A double-brake block arrangement is fitted, and the average life of a brake block is about 5,700 stops, excluding signal checks and coasting on down grades. Each bogie is fitted with two motors geared to the axle through spur gearing, the ratio being 2.36 to 1.00.

Nose suspension of the motors is adopted, half the weight being spring-borne, and the other half resting directly on to the axle.

The motors are 200 horse-power, and have been designed on the experience gained on the Liverpool and Southport line. Solid field frames have been used, also increased ventilation provided for, and interpoles fitted. The field and interpole are vacuum impregnated and enclosed in brass cases. The temperature rise of these motors is 55 degrees Centigrade after a one-hour's run at full load. The quality of steel for field frames was investigated, and it was proved that a mechanically stronger casting could be manufactured with only a very slight reduction in permeability, and a B.H. curve is shown of two different qualities of steel, also a characteristic curve of the motor.

The vacuum-brake equipment is of the simplest possible form, and its leading features are the installation of a pump capable of releasing the brake in 12 seconds, and a brake valve which admits air to the train pipe, and also starts and stops the pumps. A separate vacuum reservoir is provided for operating the horn in case the current is cut off for a short time. In the design of the brake-valve the "dead-man's" handle is incorporated, which applies the brakes and cuts off current to the main motors.

The vacuum-pump has forced lubrication. Inlet and outlet valves are fitted in the cylinder heads, and these can be easily and quickly removed. The motors, of 5 h.p., for driving the pumps are series wound, and running at 1,000 revolutions per minute on a 100-volt circuit. This pump is operated through a switch in the brake-valve and an automatic regulator.

Below the brake-valve is a tripping-switch, which breaks the master-controller circuit when the "dead-man's handle" comes into operation, or when the motorman uses a special key for converting the brake-valve into an ordinary van valve.

Bell code signals between guard and motorman are supplied with current from a small battery of accumulators; the latter are also used for emergency lighting.

The lighting of the cars is taken from the 100-volt circuit, and the heating from the 1,200-volt circuit.

The Contractor-Dealer

Vancouver Contractor-Dealers Stage a Big Convention—Officials of B.C.E.R. and Western Power Companies and Representatives of Canadian Manufacturers and Jobbers Lend Their Assistance

[The following pages contain a report of the recent convention of the British Columbia Association of Electrical Contractors and Dealers. Regarding Mr. Goodwin and Mr. Chase, this means a certain amount of unavoidable repetition of material already published. However, these gentlemen are always saying something new or saying the old thing in a new way, so that, while an explanation may be in order, an apology is not. The whole proceedings will be found to contain valuable information for all our readers.—Editor].

The third convention under the auspices of the Vancouver Association of Electrical Contractors and Dealers was held in the Hotel Vancouver of the Terminal City on May 26th and 27th and was considered by the promoters the most successful that has ever taken place in connection with this organization which now includes in its ranks practically every electrical contractor and dealer in the city of Vancouver. There were nearly one hundred delegates registered and the proceedings throughout the two days were of a most practical character. Mr. E. Brettell, president of the association, presided and with him at the table were Mr. W. L. Goodwin and Mr. Samuel Adams Chase, both well-known figures in the industry.

The task of welcoming the delegates and visitors fell to Mr. William McNeill, assistant general manager of the Western Power Company of Canada, and no more suitable selection could have been made. Mr. McNeill who was in his happiest vein prefaced his remarks by stating that if the physical atmosphere was cool their hearts were warm. They had, he said, waited long and patiently for this convention and he thought the thanks of those present were due to the committee who organized it and who had prepared such a splendid programme for their edification.

Unrest in World Today

"I suppose we all realize," said Mr. McNeill, "that at a time like this it is difficult to say almost anything. There is so much unrest in the world today that perhaps most of us feel that the better part of wisdom is to say as little as possible and to do a correspondingly greater amount. But I do trust that the result of this convention will be to bring us together in such a way that co-operation will take a far greater place in the annals of our business life than this fierce unrestricted wasteful competition has done and that the result of our gathering together will be to produce a better relationship and greater harmony between employer and employee and between employer and employer, so that, perhaps this wasteful competition in some measure at least may be eliminated and a better and greater degree of co-operation may begin.

"I am sure we here today believe that we are fit for the tasks that lie ahead of us, realize that there is dissatisfaction at the unrest that prevails, believe that surely there must be

some way out, and it is the business of a convention such as this to try if possible and find out such a way. We have found for example that the old world as it existed in pre-war days was not good enough for us to live in and surely this lesson is also becoming self-evident that it is not enough for us simply to try and restore things to the old condition of affairs. If we do that, changes are bound to come that will be for the worse. We must do more than restore. We must build and we must rebuild so that in this reconstruction period which we have entered on there will be greater results and a greater degree of co-operation than has hitherto been seen.

"Fundamentally it is not enough for the cure of the ills that beset the industrial world today to simply grant larger wages and shorter hours, much as these things are to be desired. There must somehow be introduced a new relationship that will take the place of the present system, perhaps of collective bargaining and of the strike both sympathetic and local and that this relationship will tend to do away with the fierce and awful conflicts that have hitherto characterized labor and capital in the past. Over a century ago from the fierce fires of the French revolution there emerged the golden motto which I, at least, believe contains the secret of the world's hope and the world's deliverance. The motto was—"Liberty, Equality and Fraternity." Change those terms into more up-to-date ones and you have—"Freedom, Democracy and Co-operation" and, surely in that triple tie there will be found the banding together that will relieve and perhaps dispel some of the great conflicts that we are going through."

Present Time of Real Significance

"I do trust," Mr. McNeill continued, "that our coming together at such an opportune time as this is of real significance to this city and to this country. I would wish even for a wider significance to your deliberations as they progress. And I trust that things will be done here and accomplished that will tend to promote freedom, democracy and co-operation in the highest form. Remember that those things cannot be accomplished unless by that word "sacrifice" on all sides to this question. But surely what we have seen in the last four years will give us hope. If our men went through four years of hell for these important things for which they fought, and so many have died, and others, as we see, are maimed—surely with the bigger things settled, these other matters pertaining to labor and capital and employer and employee, however big the are—this greater thing, the freedom of the world, the democracy of the world and the fraternity of the world as we see it among the great nations today can also be settled too."

"So that I am delighted," he concluded, "to find at this particular time so many of you attending this convention today. I trust that your deliberations will be fraught with the highest and the best possibilities for the good of our country and I believe with the opening of this convention there will be spread abroad in our hearts and minds a feeling of co-operation and fraternity that will produce good results and that co-operation will be the keynote of this convention."

A glimpse of what is being done in eastern Canada in the matter of organization was given by Mr. F. Jno. Bell,

general manager Canada Wire and Cable Company, Toronto representing the Manufacturers' Association of that city. Their association had, he said, been formed for mutual benefit and also with the idea of getting together with other sections of the industry, particularly in view of the general misunderstandings that had obtained in the country and between the east and west. One point he laid emphasis on in their constitution was that there was nothing to restrain a firm or any member of the association at any time getting such prices and terms as he pleased and each member could compete for business as he wished as if the association did not exist.

On behalf of his association he extended hearty greetings to the Vancouver organization and trusted the day was not far distant when all their associations might be united to bring about a better condition in their industry. The jobbers in eastern Canada were also organized, said Mr. Bell and their objects were the same as the manufacturer. One thing he asked the meeting to do and that was to promote the sale of Canadian-made goods. He felt it was necessary to do so if they were going to be able to pay their debts to other nations. Most of their electrical goods came from the United States and while they all had a friendly feeling for that country he did not think the U. S. would feel hurt if Canadians tried to sell all the goods they could in Canada and by that means were better able to pay their debts.

Praised the Goodwin Plan

Mr. Frank T. Groome, sales manager Benjamin Electric Company of Toronto, took the opportunity of thanking the association for the fine time he had experienced last year on the Pacific coast when, as he said, he was treated like a prince. Referring to the Goodwin plan he had bumped into this question perhaps more than any other member of the trade. His talks to the contractors in the east had always turned on the Goodwin plan and some of the comments on that plan were very refreshing. As he thought over the plan he had come to the conclusion that what Mr. Goodwin was teaching was a system of, or a new idea of, salesmanship. The modern sales method was to find out what would be of benefit to the customer and that as a rule would benefit humanity. It was along those lines that Mr. Goodwin was working. Mr. McIntyre said it was a plan of common sense and was nothing more or less than applied christian ethics. If a man did what he was taught to do by the moral law he was going to live according to the Goodwin plan.

Accounting Showed a Loss

Mr. J. Ross Smith, Montreal, of the Northern Electric Company's accounting department, placed a new aspect of the business before the meeting when he stated that it required \$4 to handle an average order. That included selling expenses and all the incidentals. If they made a sale of \$25 and figured their profit at 20 per cent. they would make \$5 profit. But if they took \$4 from that for expenses they would have only one dollar left. The average value of an order was small so the profit was much less than appeared on the surface.

Tells of Interesting Experience

The experiences of Mr. R. E. Callaghan, manager Toronto branch of the Majestic Electric Supplies Ltd. were highly interesting indicating what he had to contend against to get a footing on the commercial ladder. He had always thought that it was quite possible to do something for himself by trying to believe what he asked other people to believe. If they sincerely meant their intentions, they were bound to succeed to some extent. The object of manufacturing merchandise was to supply the public. They could do this to the best possible advantage and in the most efficient way by seriously

considering the public. Personally he had never attempted to do anything in the way of merchandizing an article without first absolutely convincing himself that it was worth while.

"A dealer can do absolutely the same as any other man in business—the dealer of electrical appliances—by trying to treat himself and his fellowmen the same," said Mr. Callaghan. "Occasionally we have a dealer and a jobber, and sometimes a manufacturer, who takes it into his head that he can make headway by cutting prices on the other fellow when the article has a standard price. It has been my experience from close observation that when one particular individual in any unit begins to feel that he is not getting enough business and, in order to get it all, cuts prices against his neighbor who has as good a right to exist and do business, something is wrong.

Reaching the Public

"There are only two ways to reach the public—personal salesmanship and advertising. The largest manufacturers in the world spend fabulous sums for advertising, exploiting their wares to the public. They create an interest at the opportune moment for their article. That appeals to the emotions of the buying public. But all of that would not amount to much if they did not follow it up by hard and persistent and personal salesmanship. We can do the same as the large manufacturer does. How? By paying attention to the business, talking continually, only not as a nuisance."

Mr. Callaghan cited his own experience in the starting of the company with which he is identified and stated that every article sold by him was so much to the retailer as he turned all the money into the retailer's pocket every time he sold a Majestic heater. Now all the jobbers and dealers were selling the heater and all of them could do the same thing if they went about it the same way. "Pay attention to the customer when he comes into the shop," said Mr. Callaghan. "You can buy from that customer something which is just as valuable to you as the article you are selling to him. You are going to buy ideas. There is no customer talks to you about a contracting job but what you can buy something worth while by paying attention to him."

The Get-Together Movement

Speaking of the Get-Together movement, Mr. Callaghan said he was absolutely convinced that if the electrical association that was now practically organized in Ontario, that of the manufacturers and jobbers of Ontario, if that was extended until it was Dominion-wide and if the secretary of that association was the man for the position, he believed that he could regulate things in the course of a very short time where they would have no trouble, at least in Toronto.

In Montreal there started recently half a dozen dealers cutting prices. He was called down to see them and he invited them to luncheon. He pointed out to them they were making a mistake and as a result of that luncheon he had favorable results. There was not a man there who did not agree with him that their policy was a mistake and they did not do that any longer. Continuing, Mr. Callaghan said they should figure their competitor the same as themselves. There never was a time when the Canadian public had more money to spend than today and there was no reason why the electrical trade should not get some of that money or they would find that some more aggressive fellow had been on the job before them.

"You must do something to get that money. And what is that thing?" he asked. Nothing but "mind your business." Make up your mind that you are going to improve the sales from today or tomorrow or the beginning of next month. How? Simply by convincing yourself that you have got the stock the people want and that you are going to tell them. You are going to convince some person in your community

that you have something they want and that the price is right and the first thing you know your business will increase and it will only be because of your effort."

Bouquets for Vancouver Association

Short addresses were given by Mr. J. Pim, district manager of the Canadian General Electric Company, Vancouver, and by Messrs. Read and Little, during which they welcomed the convention to Vancouver and expressed the hope that the result of that gathering would be to the benefit of the electrical industry. Mr. Pim stated that the members of the association of Vancouver had stuck together very closely and had met with a large degree of success and what they wanted to do now was to absorb the principles that had been enunciated to them. Mr. Little apologized for the absence of Mr. A. J. Soper, distribution manager of the Northern Electric Co., Montreal, and added that while he had been in B. C. there had been a greater degree of co-operation in the electrical industry than ever he had seen before. A suggestion was made by Mr. Read that there should be formed an Electrical Club and it was his intention to go ahead with such a plan which the president assured him would have the support of every member of the association.

Mr. C. H. E. Williams, who organized the Vancouver association three years ago was called upon for a short address but contented himself by stating that he was satisfied with the results of his work and that he was delighted to see the convention in Vancouver this year.

Some Goodwin Pointers

In the course of a short address before the adjournment for luncheon, Mr. W. L. Goodwin hit the nail on the head with the following:

"If we are going to co-operate we must have some sort of definite plan upon which to launch our activity."

"This great structure we now occupy is the result of a lot of planning and of several specifications and a great many minds have been brought together to build it. If instead, each man had an idea of how the hotel should be built and that he knew better how to build it, we would go back to biblical times and we know the results."

"We have a task in this electrical industry and if someone comes forward with some kind of plan no doubt the task will be well performed."

"There is something about religion that appeals to all of us in its various forms, because, after all, someone is going to decide whether our life has been well spent or not."

Continuing he said that the electrical industry as well as every other industry must not forget that at times they had forgotten there was a supreme power that was going to decide for them and very recently they had learned that that supreme power was the public. "How many men," he asked, "have given really serious consideration to the public? There has been that dominating spirit of selfishness throughout industry. The ideal dominating until a short time ago seemed to be the almighty dollar. We were driving on at a mad pace for a false goal set before us and we learned from the lessons of the great war that commercial supremacy was something to be worked for, and things got so bad that the people of the world had to get together to defend themselves.

"In a similar degree," he continued, "we have practised these same things in the electrical industry. Our mental equilibrium brings us into unison or separates us. All men are not perfect and are not of the same mental proportions and very few men are mentally sound in every respect. The degree to which we bring ourselves into mental equilibrium will lead to success or failure. If you, gentlemen in Canada bring yourselves near mental equilibrium then success is assured, bearing in mind all the time that the public is going

A group of delegates at the big Vancouver convention of electrical men from all over Canada—President Brettell, W. L. Goodwin and S. A. Chase in foreground.

to be final supreme court and render a favorable or unfavorable decision. The commitment against law is subject to certain punishment and that is the only way the peace of the country can be maintained.

"We have never," Mr. Goodwin said, "had in industry any penalty for a criminal or immoral act and that is because we were not organized. Men in our midst committed acts we knew to be immoral but, through lack of organization we had no way to punish the guilty. In a small way the organization of the electrical industry will pass decision on the acts of men and they will reward or condemn them according to their acts. That is the lesson we must teach to our brothers in the industry. And the only way we can teach that lesson is through this collective bargaining by your organization.

"I have marvelled that someone did not start long ago to organize the electrical industry not only in the western continent but the whole world. The great principles are being carried on by individual effort and no great undertaking can be accomplished in that way. The greatest good will come to the people of Canada when you so develop yourselves that you will be able to supply everything produced from your factories. The people of the United States and other nations, of course, will gladly supply you with anything you need but your success is going to depend upon your ability to produce these things which you yourselves consume and I am sure the broad gauge minds of the electrical industry of the United States will do everything they can to bring about that very desirable development in Canada.

"I know," Mr. Goodwin proceeded, "that the men who come over here to help you in this co-operative work have no selfish motives behind their effort. We have learned a lesson in the last four or five years that we are not likely to forget. We must freely contribute our services to the undertaking without any regard to the personal reward. We must make sacrifices, and if we enter into the work with that spirit, believing we will do good for ourselves and the people around us by co-operating with the other fellow, then we will at least have the satisfaction of a reward that we have been true to humanity. We must do something to lift humanity out of this gutter of selfishness and we now see in co-operation, a reflection of that spirit in the electrical industry in Canada today, something that is badly needed.

"These ills of the industry are now due to the fact that you have no organization to bring men together to get them into mental equilibrium. If you bring men together your troubles are eliminated in the spirit of good fellowship, and the desire to do good to others. I have felt in the last four years it was very unfortunate for me, due to my physical condition and age, that I was not able to give my services to the great people on the other continent. When I found that I could not go to Europe and do my bit, I undertook two and a half years ago to see if I could not contribute to bringing men together on this continent, and prepare ourselves for the great task that is bound to follow the war. If we can give our services and our life in the battle of freedom, why should we not give an equal proportion to the tasks at home.

"I have no desire or intention to submit a definite plan for your consideration that might be claimed as the only plan, but I hope it will develop at least the basis for some kind of plan modified in such a way as your local needs may require, so that you may struggle with these great problems before you. Because after all no other industry has endeavored to render such services to humanity as has the electrical industry, and if we bear in mind that we are in an industry that demands our all, and we give it up freely, I am sure our reward in this world and in the world to come, will be all we will anticipate."

Merchandizing from the Point of View of the Central Station

At the luncheon which was given the visitors by the Vancouver Association, and at which Mr. E. Brettell presided, an interesting address was given by Mr. W. G. Murrin, assistant general manager of the B. C. Electric Railway Company. In the course of his address which was based on the topic "Merchandizing from a central station's point of view," he said:

"I have been asked to say a few words on the subject of merchandizing from the point of view of the central station and I would like to say how very much I appreciate the honor of having been asked at all to speak at this important gathering.

"The convention which is being held today and tomorrow is a very welcome and pleasing indication of the progress and vitality of the electrical dealers and contractors in this city.

"I have for some time past felt very selfishly pleased and gratified to note the development that is taking place, for this is most obvious to the casual onlooker, and the go-ahead appearance of the electrical stores indicates very closely the increased energy and health of the electrical business in this city.

"That this improvement has been in some large measure brought about by the invaluable work carried on under the auspices of the National Electrical Contractors' and Dealers' Association I am perfectly certain, and seeing that a healthy live energetic body of electrical contractors and dealers is a very important factor in the financial success of a power generating and distributing company it is not necessary for me to label the fact that I very sincerely wish well to the International Association. But to come to the subject of 'Merchandizing from the point of view of the central station.'

"I think it can be fairly said in the last instance that the motive behind every business is a selfish one. By this I do not mean that businesses are necessarily run on narrow lines, but rather that the breadth of view and sound principles adopted by any particular business are adopted wisely because they have been found to pay. For instance, honesty is the best policy because honesty has been found to pay if the matter is looked at from a broad point of view; and this applies to many of the accepted dogma, although the connection is not, at first sight, obvious.

"Assuming that there is this selfish motive underlying the business of the central station and the business of the electrical contractor, I just want to examine the connection between the two and see where it leads to. From the selfish standpoint we commence by believing that the capital invested in the central station and in all pertaining to the supply of power was so invested purely with the object of bringing in an annual revenue sufficient to justify the tying-up of the capital in the first instance.

"Now exactly the same applies in the case of the electrical contractor. He puts his small or large money into a business hoping for a return. In the case of the smaller man he supplements the capital by his personal services; in the case of the large contracting company, the man putting the money in frequently pays someone else to put his personal services in to see that the money so invested brings an adequate return.

The central station is designed to supply power, and it is from the sale of this power that it must obtain its revenue which will give it a return on the capital invested.

It may be that the buildings and equipment necessary for the sale of the power may be particularly suitable to earn

revenue from other sources, such as the sale of appliances, lamps, motors, etc. If this is so then the central station is absolutely entitled to get whatever revenue it can from any source of this nature to help pay the return on the capital invested. Its primary aim is to make a profit.

"The contractor carries out wiring contracts, sells fixtures, appliances, etc., and from the profit on these he hopes to pay a return on the capital invested and for the service he puts into the business. As a contractor he has no interest in the first instance in the sale of power; he is interested in the present and eventual profit arising from the sales and transactions that he engages in and in this alone.

"So far there is practically no connection between the central station and the contractor, and unless there is a selfish reason why there should be any departure from this isolated position on the part of the two, mere sentiment will never bring them together.

"I might here mention that in the case of the central station the investment is, as a general rule, very heavy, and in consequence the amount required to pay a return on this investment is so large that the side lines such as the sale of appliances, lamps, etc., play a very small part in relation to the revenue derived from the supply of power.

Large Amount Invested

"To quote our own particular case, we have fifteen million dollars in generating plants and distribution lines in this district, whereas probably the combined capital of all the electrical dealers in the same district would not exceed half a million dollars, so that you will see at a glance how overwhelmingly important the sale of power is to the central station as compared with any other issue. Now just for a moment let us examine where the two come together and where they lie apart.

"In order to develop the sale of its product the central station must:

1. Retain its old customers,
2. Obtain new customers,
3. Encourage the use of any current-consuming devices which the public can reasonably be expected to purchase.

"To bring about the first the customer must be satisfied, and dissatisfaction can arise from a number of causes.

"An intermittent or irregular supply of power for instance. This is a matter for which the central station can be entirely responsible, and, in fact, to ensure it, spends many millions. In our own case we have three separate transmission lines to ensure against breakdowns and have a costly steam plant standing idle purely for the purpose of coming into action and taking the most important part of the load in the event of a mishap to the hydro-electric plant; beyond this, the hydro-electric plant itself is constructed on the most permanent and expensive lines. If it were not for the anxiety of the central station to give satisfaction by ensuring the certainty of supply the cost of the apparatus to supply the consumer could be very much less than it is in our particular case. This in itself is evidence of the most tangible form that the central station places a great value upon the fact that its product must give satisfaction.

"But dissatisfaction may arise from a source over which the central station has no control. The wiring of a house may be carried out on cheap unsatisfactory lines and interruptions to the supply may occur from this cause and neutralize the millions of dollars spent by the central station to ensure regularity of supply.

"Here then, I think, we have the first point of contact. I know that this argument is reciprocal and that the contractor has a legitimate kick if he is carrying on his work on sound durable lines to give satisfaction to the user of electricity and the central station neutralizes his work by giving an irregular supply and discouraging consumers and would-be

consumers from placing further orders for electrical wiring and equipment. But the title of my subject is merchandizing from the point of view of the central station and it would take too long to examine from both points of view all the time, therefore I am sticking particularly to my subject.

"Is it not clear that the central station must ensure by any means the high standard of work, that where appliances are used they must by every means in their power see that they are such as will give satisfaction and encourage rather than discourage their extended use?

"The contractor today sees very largely eye for eye with the central station in this particular point for he is long-sighted enough to see that the satisfaction of the consumer is practically as important to him as it is to the central station, and the existence of a body unifying the contractors and leading them by a wise policy to follow the best lines, assists very materially in this matter.

"There is always a danger that seeing the contractor gets his profit in the first instance from the work carried out or the sale of the appliance, that he will in the one case do cheap work so that he may put in a low price and get the business against competition, or in the other case sell an unsatisfactory appliance to get the profit on the sale, rather than not sell anything at all; and, therefore, the central station has to protect itself, and in some cases at considerable cost; establish standards, and protect the public and the short-sighted contractors against themselves. I do not think I need labor this point, for this is one of the reasons why, apart altogether from the question of cost or profit the central station sometimes undertakes merchandizing on its own account.

Wiring in Private Houses

In connection with the quality and design of the wiring installed in houses the fact that there are government regulations controlling this takes a certain responsibility from the central station, and is, in my opinion, a very good thing. The government has not yet established the same control covering equipment installed for the supply of gas, and as a result the Gas Company is continually fighting to maintain a high standard of installation, and the principal opponent is the man who, in order to get a contract for fitting a building for the supply of gas, quotes for undersized pipes and equipment so that he may be able to put in a lower price.

"I stated that the second point necessary to the central station in order to develop the sale of its product was to obtain new customers. Here the interests of the central station and the contractor are distinctly in line. The more popular the electrical service and the greater the encouragement given to the man who has not yet equipped his house, the better for central station and contractor alike. Today there is practically no competition with electricity as a lighting supply and practically every house readily accessible to the distributing system is only too anxious to get equipped. The contractor may sometimes take issue with the central station here inasmuch as the customers are ready to be connected and the central station will not connect them without a considerable proportion of the connection expenses being borne by the customer himself. Here again it is a case of profit that fixes practice.

"The central station wants new customers but it does not want business that can only be carried on at a loss. We will connect any man where the connection costs are not more than three years gross revenue from that man.

To Defray Cost of Service

"If you analyze this you will find that in the case of consumers of this class fifty per cent. of his gross revenue goes to off-set the fixed charge on the cost of connecting him, and fifty per cent. only is left to defray all the cost of giving

him service, together with his proportion of the responsibility for the enormous capital invested.

"Deduct from the average consumer's bill the cost of giving him service and, under the condition mentioned above, practically nothing remains to set against the cost of supplying power and we make no profit under these circumstances. This is as far as we can go; to go any farther than this would mean that we are far better off without the consumer than with him, and under these circumstances the contractor must not get sore at the central station for refusing the consumer's business unless he can put up a connection charge commensurate with the outlay.

"It is under the third head of Encouraging the Use of Power-Consuming Devices that the most interesting point of contact arises between the central station and the contractor. I pointed out that with a heavy capitalization the central station must develop the sale of its power at any cost, and power can only be consumed through power-consuming devices. Therefore, the central station is very much interested in the development of the use of power-consuming devices. If it urges the use of power-consuming devices which do not give an adequate return in usefulness for the power that they consume then it defeats its own end by making the device unpopular and discouraging in general the use of power."

Mr. Chase Urges as a Motto for the Electrical Industry—"Live and Help Live"

Mr. Samuel A. Chase briefly addressed the convention on resuming their deliberations after luncheon. He considered it a great opportunity he said that the closing work of his life was associated with Mr. Goodwin in the task that he was so ably carrying out. After he had heard Bill Goodwin in New Orleans some few years ago, he could think of only one slogan, and that was "Live and Help Live."

In analyzing the various difficulties in the way of perfect harmony and co-operation in the United States, he had made a few notes, some of which had already been touched upon. The principal difficulty had been selfishness, in that each individual and each class had thought himself and his class the best without considering the other classes in the industry. "I think," said Mr. Chase, "that all classes have disregarded proper business ethics. If you call on the professional man say, or your physician, the first question he will ask is who has been attending you. If a waiter is waiting on you at the table, another waiter will not help you with your breakfast. Yet, in the electrical business we look into the other pasture and see it is pretty green, and we forget business ethics in our eagerness to get into the green pasture of our competitor.

"Another difficulty as I see it, is that we have had no definite plan of merchandizing. I do not think we have been ready for a definite plan until Mr. Goodwin came on the scene in the east, and the difficulty in the way of a definite plan was the lack of education menacing various classes. The manufacturer did not look on the jobber with the right attitude of mind, the jobber did not look on the contractor with the right attitude of mind, and so on through the industry.

"But now and for some time we have been ready for a definite plan, and we are putting this definite plan into effect. The principal difficulty in the way of this plan is that the various classes do not recognize the services rendered by the other classes. Another very important point, and one that has caused a great deal of trouble is misunderstanding. Misunderstandings arose because we did not get together, and iron out our difficulties. I do not think any of the various classes, the manufacture, the jobber, the central station, or the contractor dealer, desired to do any of the other classes any

injustice, but it is just through lack of this education and knowledge of the other fellow's problems, and also the fact that they cannot understand each other's language that these difficulties have become mountains in the eyes of the electrical industry.

"It is only through getting together with open minds that all these various difficulties fade away into insignificance. The spirit of the times seems to be to get together, not in an illegal way, but to discuss various problems, and iron them out, and get acquainted with one another. You may be interested to know something of the progress that we are making in the United States. In California and Oregon the situation seems to be pretty nearly a hundred per cent. That is principally due to the fact that Goodwin planned a good many years there before he went east. The situation in the balance of the States is that it is good in some spots and bad in others, but it is improving all the time, and there is no situation too bad but we feel we can get good results.

"Make love to your competitors." You will get along a great deal better, and you will find they are all good fellows. I have no hesitation in saying that in the parts of the country we have been cultivating, we will get good crops. The National Contractors' Association never was as prosperous as at the present. The National Association needs you because of its prosperity. At the same time the National Association wants to have a hundred per cent. membership among the contractors.

"Individually we are weak," said Mr. Chase in conclusion. "None of you can accomplish much, individually, with the manufacturer, but collectively, that is from an association standpoint, you can accomplish anything that is right. I want to make a strong plea and leave this thought with you, that is, to apply this slogan personally, and in your business—"Live and help live."

In the Evening Mr. Goodwin Addressed the Banqueters—The Wheatstone Bridge Again

The feature of the evening banquet was the address delivered by Mr. W. L. Goodwin. There was a very large attendance and the address was listened to throughout with close attention. Mr. Goodwin occupied an hour and half in delivery and used a diagram to illustrate some of his remarks. He made it clear that without organization the electrical industry need not expect to make any progress and that the system that had prevailed of always being at each other's throat was not going to get them anywhere. It was a masterly exposition of the position of the members of the electrical industry. In part, he said:

"The men of the electric industry have been greatly derelict in their duty for a long time, and it is my task to travel about the country and tell men their faults in language they can understand. We have got to learn much to our sorrow, that there was something wrong in the world in the last few years. Just what it was we did not know. We permitted this wrong to drift on for many years until it came to a climax in this war. The system in the world, from the standpoint of commercial activity, is wrong and must be changed. I think we all admit it is wrong, and many of us know wherein it is wrong. But due to that selfishness which human nature displays, we hesitate to do anything towards the changed condition.

"The ideal for which we have longed in the past, has been the wrong kind of ideal. Success in later years has been measured by financial prosperity, and when you make the measure of success the almighty dollar, without any respect to the means by which that success is gained, you are bound to precipitate a world condition that sooner or

later, is going to end in disaster. That is just what has been happening in the world. This state of war between nations is due nearly always, to economic causes. Trouble or friction, or competition between interests is invariably due to economic conditions, and to remove the trouble you must readjust the economic situation of the world, or of the economic situation existing between competitors. That is very simple to understand if we will take the time to analyze the situation.

"Some people take great delight in erecting monuments and contributing their resources to communities, but I prefer to devote my time to the development of humanity in a field of endeavor which I understand. So I have elected to devote my time to causing people in the electrical industry to understand the underlying economic causes which precipitate vindictive competition. We have a very complex situation to deal with. I think there is no other industry that has such a multiplicity of problems to deal with as has the electrical industry. We have all the problems common to finance, management, accounting, merchandizing, selling and warehousing. Then we have the more intricate problem of relationship between great public utility companies operating sometimes under private charter, and operated sometimes by municipalities.

"We have the great problem of engineering and development in order to advance our industry—not common to any other industry—and we have the more intricate problem in that the incentive to succeed varies to a large measure with the different groups who are interested. The incentive to prosper on the part of the public utility company is entirely different from the incentive to the electrical contractor which is also different from the incentive to the jobber. We have these four great groups in the electrical industry of public utility companies or central stations, manufacturers, wholesalers or jobbers, and contractors and dealers or retailers. Without a full appreciation of the problem before us, we set out twenty years ago to organize these four great groups for purely selfish interest. I am sorry to say I was one of the pioneers, and as I understood the situation at that time, we organized the jobbers of the United States for the sole purpose of advancing ourselves against the other groups in the industry. At no time did we ever consider the economic problems that confronted the electrical industry.

"Meanwhile the central station industry was organized along similar lines, and the manufacturers and the retailers as well, until we built up these four great group organizations, and these four great interests have been at each other's throats over twenty years trying to destroy each other. Men blamed one another for the faults that they developed, and there are so many faults—some one has called them the ills of the industry. They have not been very serious because of the rapid development of the industry, and the unknown commodity we have sold has led to unusual profits, and the public have paid the price without knowing the value of the services rendered.

Relative Value of Electrical Energy

"In the electrical industry we have no known relative value due to the fact that we do not understand it. No man has been able to define electric energy. We know what it will do, but when we are asked what the thing is we are selling, we do not know. We have never been able to measure its real value, evidenced by the fact that in the United States you will find as many rates for electrical energy as there are central stations, some three thousand rates or prices charged for exactly the same commodity. We have not employed any scientific method to arrive at a value of the commodity we sell. Competition has not perhaps reduced us to that state where we have felt the necessity of

coming down to mother earth to determine the real value of the commodity we sell.

"The great public utility companies of the United States have concentrated on the most miserable type of advertising. These great public utility companies have a message to deliver to the public, something to tell them about electricity and what it would do in simplifying living. But instead of doing that, they select the cheap common method of bargain sales advertising. For a period of years one of the largest companies never placed a single advertisement except a bargain sale article. That convinced me we have had a wrong conception of our industry.

Organized Into the Big Four

"We have organized these four great groups, and they have become powerful interests, but what do they consist of. We have in the United States, 25,000 electrical contractor-dealers, 175,000 other retailers, including department stores and hardware stores—200,000 stores engaged in the retail electrical business, without any semblance of an organization to bring them together to work for a common interest. We have 1,900 electrical manufacturers, and no common relationship between them. They employ 700,000 men. Then we have 5,000 public utility companies supplying power, and no means of bringing them together. The whole industry employs 7,000,000 people, and this conglomerate mass of interests have been struggling with this problem, and have been at each other's throats for twenty years, on the principle of the survival of the fittest. Is it any wonder that electrical men in Vancouver struggle with the problem, and are unable to get an answer.

"Our engineering problems have been handled in the most efficient way. We have provided simple formulae and when an engineering problem is presented we apply one of these and in a short time we get the correct answer. But when it comes to merchandizing it is each fellow for himself. One man in Vancouver said he preferred to go alone. That is unfortunate and we cannot permit that to go on. The labor unions were organized because men were unable to go alone and they just had to organize themselves in order to defend themselves and because there is not a right relationship between capital and labor there has been set up a condition in this country and in the United States where might is presumed to be the deciding factor in a controversy today. Power will never settle any dispute that arises between capital and labor.

"The economic cause that precipitates the trouble must be removed, and, if we analyze the economic cause we can determine the right answer and, if capital on the one hand, and labor on the other demand to exercise their power and control the situation without any respect to the underlying economic cause it is naturally the signal for further retaliation and the other side strengthens its position so that they can come back. When we find any old problem we must get right down to the underlying causes that precipitate these difficulties and have a clear idea of what the underlying cause is.

Vicious Thing in Modern Government

"The most vicious thing that has been set up in the modern government is the desire of politicians to appeal to the popular sentiment without any regard to the merits of the case at issue. Politicians are keen to sense public sentiment and they go that way whether the public is right or wrong. And that precipitates trouble. We expect our leaders to lead us along the safe road but simply for political popularity they lead us to disaster. An so we must have in the days to come a new type of politician, men who will respect honor rather than a simple desire to please for the moment."

Speaking on the question of co-operation, Mr. Goodwin

said the general idea was to let the other fellow do all the co-operating. There seemed to be a sort of human desire to precipitate jealousy between the great powerful corporations and the small individual company. Men took a delight in criticizing the methods of the great corporations and perhaps at times they were justified. But they seldom ever gave the devil his due and were it not for the great pioneer work done by the corporations particularly in the electrical business he questioned very much if the city of Vancouver would be here today. It was only through these corporations that this virgin country of Canada could be developed. What chance would a lone man have if he delved into this great wilderness, of converting it into a thriving country?

"What we must do," continued Mr. Goodwin, "is to find some means of common interest and common relationship between those widely-separated interests. And I say that co-operation is the means of bringing us together. But not co-operation in an abstract way as it has been put for years. In other words we must be prepared to do one or two things. Either we must find a common ground upon which these two widely-separated interests can meet or we must pull the corporations down to the level of the little man or lift the little man up to the level of the corporations. How are we going to do it? We are going to do it by clear understanding of the economic causes which precipitate trouble between the various groups in the electrical industry.

And What About Trade Discount?

"There is one thing I want to say and that is that we have not had a clear conception of trade discount. Very few men, if any, in the electrical industry have a clear conception of the difference between trade discount and compensation for services rendered. The trade discount has come to be known as the medium of exchange allowed in discount for quantities purchased and that is quite distinct from what I call compensation for services rendered. We have never had a scientific treatment of this broad question of trade discount. An

analysis of the statement of 1,800 jobbers and manufacturers develops the fact that not a single one took into consideration the economic problems involved in distributing a particular commodity. We make not relative distinction in prices or discounts based on handling goods and, goods are sold from producer to consumer without any regard to the cost involved in distributing or selling. This must be corrected.

"Compensation for services rendered has never been understood and, because of that we have developed a situation whereby two stores, one a jobber and the other a contractor-dealer render exactly the same service to the same purchaser and receive compensation varying at times as much as 50 to 100 per cent. The condition under which we are living are what I call immoral in the electrical business. The men have grown up to be selfish. They have been set against this great force of competition without understanding what it is about and have become selfish and the men of Vancouver in the electrical business are no different from what they are in other parts of the world.

"Manufacturers and jobbers and very often the public companies have preferred to keep the contractor and dealer in ignorance. Whenever we get to the bottom of this subject and start to talk real problems someone says let us iron out our difficulties and we will have a closed meeting and in that way we keep in ignorance the other groups. It is only in the last two years we have developed to a point where we frankly discuss these problems before our competitors and in that way we get to an understanding of the other's problems. It is a process of commercial education and when men are educated to that extent they can go on and prosper.

How to Study Their Problems

"How are we going to present to the men in the electrical industry a clear understanding of their problems?" Mr. Goodwin asked. "Can we do it by discussing our selfish interests of group organization? No. We have tried that and it does not work. We must find a means of bringing all the men to-

Mr. Goodwin uses the Wheatstone Bridge to illustrate his plan of co-ordinating the various sections of the electrical industry—manufacturer, central station, jobber, contractor-dealer. In the Wheatstone Bridge, prosperity, (the galvanometer), is stabilized only when each section is working in balanced unison with every other section.

gether to handle our problems and let each man have an understanding and set out to correct our ills. The jobber occupies an undue advantage over the contractor-dealer in his ability to compete. When the jobbers clearly understand the advantage they possess and, knowing they have that advantage they are willing to give up certain of their rights and place themselves on an equality to sell to the contractor-dealer, their position is going to be preserved and if they are not big enough to realize the situation and voluntarily give up the advantages which they enjoy, then the electrical industry must take away from the jobber that thing which is preventing us getting together.

"If the great utility companies of Canada and elsewhere precipitate a kind of competition with contractors and dealers in the sale of appliances they produce unfair competition or a kind of competition that the contractors and dealers cannot meet, then we must go to the public utility companies and point out the error of their ways and if they are real men they will give up their advantages. And if they do not, we as electrical men must organize to see that this practice must cease. By that I mean this—that a great public utility company, primarily engaged in selling energy must not parasite the appliance business at the cost of the dealers and jobbers.

Immoral Practices in Trade to Cease

"I have no idea of asking any concern," Mr. Goodwin continued, "to give up part of the business they are engaged in but I do insist they cease this practice of unfair competition, this immoral practice in taking advantage of the other fellow. And if we are not big enough to see that situation and correct the fault ourselves we must expect the power to be developed that will take that thing from us. The judge of this whole thing must be the public. They are going to decide whether we have acted fairly and wisely. And some of the things the public are doing today and the opinions they form about the electrical business, perhaps are founded on the fact that we have not acted wisely and well. And so we must start a new order of things. We must determine every fault in our industry and set ourselves to correct those faults.

"The first fault is lack of proper organization. It is only recently you had any semblance of organization in Canada. And I think you will agree with me that, as a result of the pioneer work on the part of Mr. Williams, Mr. Brettell and Capt. Conway, that a spirit prevails which would never have been possible in the days you were without organization. Carry that spirit along and bear in mind all the time that your success will be measured by your efforts to satisfy the public."

Mr. Goodwin mentioned that every year the electrical industry of Canada and the United States must have \$600,000,000 for development work and how could they expect that money from the four groups of the industry if they were fighting for supremacy. That money, he added, must come from the public. And so their first problem was to establish confidence in the public. It was obvious that the public were to the one determining factor in their problems. He was against bargain sales or instalment sales. Any of these in reason were good business. But the bargain sales that started at the beginning of the year and ended on December 31st no longer appealed to anyone.

From a Scientific Standpoint

The solution of their commercial problems depended on a careful analysis of cause and effect and to do this they must approach these problems from a scientific standpoint. They should bear in mind that they need not be engaged in so-called scientific problems in order to apply scientific methods. If they approached this question in that way they would get

an understanding of the factors involved and then they would approach the problems without bias or suspicion.

"What does this plan mean?" he asked. "It is a campaign of commercial education. We must develop a condition of things when men and women must have a means of continuing their education so that they are adapted to meet the average problems that confront them. Education in commercial activities must come through the medium of the trade organization where we have a free exchange of ideas. And so this plan of mine reduced to a simple statement is a campaign of education, educating members through trade papers, trade organizations and other channels and bringing together the various units in the electrical industry.

"The basis of the campaign," said Mr. Goodwin in conclusion, "is that each individual owes a responsibility to the organization, that the organization owes a similar responsibility to its member, that each organization owes a responsibility to the other organizations in the industry to the end that all problems may be discussed having in view the interests of all."

Explains the Wheatstone Bridge

In using the Wheatstone bridge as a method of illustrating his remarks, Mr. Goodwin explained that the Wheatstone bridge furnishes an excellent analogy of the method of scientific merchandizing in the electrical industry. The battery, the source of energy, represents the public whose investors furnish the capital for all branches of the industry. This capital, the manufacturer converts into generating and distributing equipment for the central station or industrial, or into appliances and supplies. His sales diverge as shown in the diagram, dependent upon the principal class of product utilized by each branch. The central station has electric service as its principal product which, it will be noted, is used through the wiring installed principally by the contractor-dealer. The wholesaler has as his principal function problems affecting wholesale electrical merchandizing. He makes contact with the central station or the contractor-dealer in passing to the consumer. The contractor-dealer thus becomes the point of retail contact of the manufacturer, central station, and wholesale with the consuming public which, by the way, following the circuit, brings us back to the negative side of the battery, thus completing the analogy.

Nothing in the diagram indicates, nor is it the intention to restrain in any form, either of the interests referred to in performing the function of another, but due regard to the interests of all should be recognized in order that the scientific plan of merchandizing under the Wheatstone bridge principle will not indicate on the galvanometer an unbalanced condition which now exists.

When each interest operates with a due regard to the interests of the others the galvanometer will indicate at zero, an evidence of a balanced condition which, when applied to electrical merchandizing and the electrical industry is reflected as stability and prosperity.

A Heart to Heart Talk

Part of the morning session of the second day's proceedings of the convention developed into a heart to heart talk between contractors and dealers and others and the answering of a number of questions by Mr. Goodwin as to the proper course to adopt in certain problems. The policy of the B. C. Electric Railway Company in selling irons at a lower price than that quoted by the other electrical dealers was explained by Mr. W. G. Murrin, assistant general manager of the company. His company, said Mr. Murrin, was vitally interested in the sale of electric energy and consequently in the sale of any appliance that would use up that power and the iron was very valuable in this respect. He stated, however, that his company was willing to eliminate

the cut-rate for one year and see the result of the co-operative sale, a statement which was received with great enthusiasm.

Need Campaign of Advertising

Mr. Goodwin emphasized the need for intensive sale methods. He thought the various branches of the electrical industry should get together and conduct a campaign of advertising. That the dealers should rise to the occasion, in view of the offer of the B. C. Electric was the statement of Mr. Chase who said he sympathized with that concern in its increasing difficulties.

Answering a question as to the benefit which could be rendered by electrical inspectors, Mr. Goodwin explained that their function should be to eliminate the unscrupulous and transient contractor. He suggested that a committee be appointed to draft a code of rules in order to safeguard life and property from faulty installation, motors and switches. At the same time, said Mr. Goodwin, the code should be flexible to provide for an expansion of business.

Replying to a question as to what the association could do if one man broke away or refused to enter their ranks, Mr. Goodwin said there were all kinds of parasites in the world. The contractor often had difficulty in selling an idea to a man.

One of the most important questions put to Mr. Goodwin was in respect to the legal aspect of the question, whether a dealer could refuse to sell to a man who was not a member of the organization. "The association in Vancouver and the individual jobber have taken legal advice and have been told that they cannot refuse to sell to a man who is not in the association," was the statement made by one of the members.

Law on a Delicate Problem

"I challenge any attorney in Canada," said Mr. Goodwin in reply, "to come into this room and tell me I cannot run my business as I please and that I cannot refuse any business that does not look good to me. I do not believe you have any laws in Canada that are tighter than the Sherman or the Clayton Act we have in the United States. There is no law in Canada," said Mr. Goodwin with considerable emphasis, "that compels you to sell to a man you believe is a menace to your business. Because that goes back to the old common law of England—the individual right of a man to conduct himself as he wishes so long as he conforms to the regulations.

"Collectively," said Mr. Goodwin, "this crowd cannot say they will not sell to a man. The jobbers can get together and if you educate each and every man you individually can go out of this room and refuse to sell to a man whom you believe is a menace to the electrical business."

"You cannot refuse to sell if he is willing to pay the price," remarked another member.

"In the United States the only people who must give service are the public utility companies who are operating under charter. It seems to me that you must figure out the class of people in your community who are undesirable. Don't do it like collective bargaining because you are likely to go to jail."

Answering other questions, Mr. Goodwin stated he was in accord with the idea of not keeping the association a sectional one. Alluding to the accounting matter he said they wanted standardized accounting methods. As to the labor question so far as it affected wages, he replied that he preferred to leave that in the hands of each individual firm and added that he always paid his men more than the union scale of wages.

With respect to the education of the architect class, Mr. Goodwin was asked how the four groups could co-operate to do so and in reply said they had to educate the contractors

and architects in order to do away with foxy specifications. They should have a committee to deal with the architects.

The matter of the appointment of a delegate to the National convention in Milwaukee from July 14 to 20 was left over to be taken up by the association.

Explaining the position of the B. C. association in regard to the national organization which Mr. C. H. E. Williams was anxious to get information on, Mr. Goodwin stated that the National Association was originally made up of 17 men on the executive committee. Six were from the Atlantic, six from the central district, two from the Pacific and three at large. When the Canadian division was formed he thought provision was made for two delegates from that division, their expenses to be paid by the division. There was some differential set up for the dues of the Canadian members so that the expenses would not be too heavy. He believed the National executive had been increased by two members, one from eastern Canada and one from the west. He understood the expenses were borne by the association.

In reply to another question as to whether the jobbers in B. C. were associated with the jobbers south of the international line, Mr. Goodwin said that was their ultimate goal.

The Open Price System

On the matter of the open price question, Mr. Goodwin stated that he would suggest they should get a copy of Jerome Eddy's book entitled "The New Competition" which dealt with this subject very fully. Meanwhile they ought to go into this Open Price Plan and try and make it effective in some way as it would inject confidence and put them in a position to successfully combat this miserable method of parcelling out bids and telling the lowest contractor what a good fellow he was but adding that he would have to cut his bid.

Mr. Chase gave a brief address on the problem of producing results after such a convention. Resolutions passed at such a gathering were often unsatisfactory because they did not produce results, said Mr. Chase. If they would take advantage of Mr. Murrin's offer he believed that good results would follow their meetings.

Before the meeting separated to be the guests of the Rotary Club at luncheon, Mr. Goodwin submitted the twenty-one points in the Goodwin plan, which he said he had not had time at the banquet to give them. They were as follows:

(1) A strong and representative association of electrical contractor-dealers (retailers) and urges all interests to lend immediate assistance to this end.

(2) That each division of the industry prepare a code of ethics outlining its own functions, relations and responsibilities to each of the other divisions of the industry.

(3) That each division establish a code of practice outlining its methods, policies, etc., in dealing with other than divisions within the industry.

(4) Improvement on merchandizing methods, better display, and the encouragement of more retailers, by urging present contractors to open retail stores, thereby enlisting the support of central stations and offering a broader and larger outlet for manufacturers.

(5) Recognition of the service functions of the contractor-dealer and recommends a differential when this service is performed.

(6) The sale of high-grade electrical material; the establishment of high-class specialty retail shops; improved specifications in wiring installations; and the introduction of liberal use of convenience receptacles.

(7) Broader education of the public concerning the problems of the electrical industry, and concerning electricity, its use, and the application of household devices.

(8) Retailers applying intensive sales methods in con-

nection with small devices used in home, factory, office, etc. (such as washing machines, vacuum cleaners, dish-washers, electric ranges, electric heaters, household heating devices, sewing machine motors, fans, lamps, portables, fixtures, vibrators, hair dryers, ice machines, etc.)

(9) The introduction and application of proper cost-accounting methods in wholesale and retail merchandizing, particularly if either function is a minor department of a company.

(10) Free and unobstructed flow of trade along most economic channels, without attempt to direct it through fixed channels.

(11) That central stations conducting retail departments for the sale of lamps, appliances, devices, portables, etc., operate same in accordance with the ethics of retailing and with full regard to proper cost accounting.

(12) That all interests conducting retail departments for the sale of lamps, appliances, devices, portables, etc., operate at a profit. The adoption of this policy on part of central stations and jobbers will result in a large number of concerns entering the retail field.

(13) Recognition of the service function of jobbers in the distribution of supplies and recommends a differential when full service is performed, and a proportionate differential when only a partial service is rendered.

(14) Jobbers determining through proper cost accounting, the cost of warehousing, and selling their principal commodities, to the end that each principal commodity will carry its proper portion of overhead.

(15) Open meeting of all trade associations, including meetings of executive committees.

(16) That the electrical press become an integral part of each division by honorary or associate membership, and that unrestricted publicity be given the proceedings of all meetings.

(17) The formation of a national lecture bureau, with state and local staffs. The function of the staff would be to carry on educational work within the industry and before public gatherings. Service to be gratuitous.

(18) Recognition of the principle that any action taken

by a single division which affects another division is seldom satisfactory unless each division affected is represented.

(19) The appointment of committees by the National Electric Light Association, Electrical Supply Jobbers' Association, National Association of Electrical Contractors and dealers, and various manufacturers' associations to meet together to study the problems of the industry and to co-operate in finding their solution.

(20) Consolidating or reconstructing overlapping organizations. A committee comprising representatives from each association should be formed to study this question and submit a plan.

(21) Eventually a single organization in the electrical industry, consisting of national, division, state and local sections; also main national sections for the solution only of functional problems of the several branches or groups.

Sparks from the Convention

President Brettell handled the convention admirably and never allowed the speakers to get away from the point of contact. He was at the switch all the time.

Secretary Capt. Conway was an able assistant and looked after the arrangements in capital style. There was not the slightest hitch in anything and the captain is to be congratulated accordingly.

One of the happiest men at the sessions was our old friend, C. H. E. Williams, the actual founder of the Vancouver association three years ago. He wore the smile that made everybody happy and he took the compliments showered on him for his pioneer work, with becoming modesty.

Among those who helped to make the convention a success were the following who constituted the programme and organization committee: Messrs. J. Read, E. E. Walker, S. E. Jarvis, J. E. Rowland, C. Moulton, J. J. Crossman, R. A. Graham, J. Duck, S. R. Smith and E. Brettell.

The committee in charge of the financial arrangements were: Messrs. C. H. E. Williams, F. Williams, H. Rees, J. E. Rowland and E. Brettell, while every member of the Vancouver association was on the reception committee.

There were no decorations at the convention, every

Mr. E. Brettell, President B. C. Association
Electrical Contractors and Dealers

Captain W. J. Conway, Secretary B. C.
Ass'n. Electrical Contractors and Dealers

member doing his utmost to bring it off with honors, and in this they succeeded one hundred per cent.

The ladies were looked after too. On the first day they were given an auto trip round Stanley Park and had tea in the pavilion where they were joined by the mere males after the latter had concluded their afternoon session.

The banquet was a humdinger. The menu was characteristically high-class, in the best style of the Hotel Vancouver and close on two hundred guests sat down. There was classical music by the orchestra and other musical numbers by professionals and members of the association who showed that there is considerable talent of this kind among them.

Living up to their slogan of "Service" the Rotary Club did the second day's luncheon up to their usual standard. Messrs. Goodwin and Chase were the speakers and they were accorded a cordial reception, as was every member of the association.

Not the least interesting feature of the gathering was the trip to the power-house of the B. C. Electric up the North Arm of Burrard Inlet. In contra-distinction to the weather that had prevailed in the earlier stages of the convention, the afternoon was fine and as a result 140 persons made the journey.

They were received at the power-house by superintendent F. Elwell and on the trip were accompanied by the following officials of the B. C. Electric: W. G. Murrin, assistant general manager; E. H. Adams, controller; E. E. Walker, sales manager; W. Saville, general secretary and James Lightbody, publicity agent.

Tea was served in the transformer room at No. 1 plant and the thanks of the association were fittingly conveyed to the company for its hospitality. In the evening the members and visitors attended the Orpheum theatre as the guests of the Vancouver association.

J. Herbert Hall, chairman of the Canadian Associated Manufacturers of Electrical Supplies wired from Toronto as follows: "This association is anxious and willing to co-operate in any way to further the interests of the electrical industry as a whole. May your convention be a success and lead to a betterment of conditions and business in this great Canada of ours."

W. H. Morton, general manager of the National Association sent this message: "Greetings and best wishes for a successful meeting from the National Association. You should elect a member of the National executive committee to be one of the two from the Canadian division. Hope you are making plans for one hundred per cent. attendance at the Milwaukee convention in July."

From Kenneth A. McIntyre came this communication along the wires: "Ontario Association sends greetings and best wishes to British Columbia Association on occasion of your great convention. Regret we cannot be represented this year but will not fail next time."

E. Jewitt, acting secretary of the Canadian Electrical Supply Jobbers' Association, had this to say in a letter after sending their greeting: "We believe that associations such as are now being organized in the electrical industry throughout Canada will be the means of vastly increasing electrical business in Canada and will put the industry on a higher plane than it has ever enjoyed."

A letter was received from Senator Frederic Nicholls, president Canadian General Electric Company Ltd., Toronto, regretting his inability to be present; also one from H. J. Gille, sales manager of the Puget Sound Traction Light and Power Company, as well as from a number of others.

Lt.-Col. T. G. Bird, D.S.O., who has just returned from the front, was expected to be in attendance but it was ex-

plained that he had been delayed coming through the mountains.

Mr. A. S. Edger, of the C. G. E., Toronto, and Mr. A. J. Soper, of the Northern Electric, Montreal, were also unavoidably absent.

Mayor R. H. Gale and Mrs. Gale were guests at the banquet on the evening of May 26 when the chief magistrate delivered a characteristic address dealing with his earlier experiences in the electrical industry.

Montreal Electrical Contractors' Organization Discuss Constitution

A Montreal Electrical Contractors' Association is now a reality. The body has the backing of the largest firms, English and French Canadian. Although the contractors were primarily brought together to consider the demands of the workers, those who attended the preliminary meetings quickly came to the conclusion that a permanent organization was the only way to deal with such questions. The preliminary meetings were exceptionally well attended, and the body quickly organized. The association will have the advantage of being affiliated with the Association of Montreal Building & Construction Industries, with its own section, officers, and constitution, and with representatives on the parent body.

The second meeting was held on May 30, Mr. F. J. Parsons (McDonald & Willson Co.) presiding. The principal business was to receive a report of a temporary committee appointed to consider the question of organization, constitution, etc. This report was presented by Mr. A. S. Henry (Canadian Comstock Co., Ltd.) who pointed out that the working men, realizing the strength that was in unity, had organized into associations. A few years ago, in the mind of the average contractor, any thought of a condition of co-operation or relation between the contracting interests and labor interests would have been classified as absurd and dangerous. The ultimate uplift of their business could, he believed, be only permanently accomplished by proper co-ordination of the interests of the employer and employee. If they were to work out on a fundamental basis the problem of labor in Montreal, it could only be done by organization and united action on the part of the electrical contractors. There was much to be done collectively in raising the standard of their work. No calling required greater skill than theirs, and yet they were regarded as mediocre; electrical contractors were important in every building operation, and how could they show the importance of their business better than by organizing, by becoming better acquainted through frequent meeting, by exchanging views, and by accepting the modern doctrine of business, publicity, price fixing used to be the order of the day and the principal function of trade organization; it had, however, never been successful, as it was not founded on sound economic principles. Co-operation in competition, in a relatively small body like their own, should be founded on an exchange of views on questions of management, organization, financing, selling, credits, forms of contracts, collections, and overhead expense and its relation to price quotation.

The proposed constitution was then read in English and French, and the first clause passed. This proposed that the name should be the Electrical Contractors' Association of Montreal, affiliated with the Association of Montreal Building & Construction Industries.

The balance of the constitution was referred to the executive committee for report.

Mr. R. Moncel (Moncel Electric Co.) was appointed president, and Mr. F. J. Parsons vice-president. The executive committee are Messrs. H. Vincent and J. St. Amour.

The temporary committee presented a detailed report

of a proposed agreement for wages and working conditions with the local branch of the International Electrical Workers' Union. This was left for further discussion.

The Association further discussed the question of a working agreement with the International Brotherhood of Electrical Workers, at a meeting held on June 5. Mr. Moncel presided.

The meeting debated at considerable length the question of recognizing the union. A resolution was proposed to the effect that the executive committee be empowered to take up with the union the question of entering into an agreement for working, and report to the Association. An amendment was proposed declining to recognize any labor union and leaving to each individual or firm to deal with the union as they seem fit. The amendment was carried.

Mr. Vincent brought up the question of the examination of wiremen and the licensing of contractors.

Mr. Simoneau also referred to the fact that many workmen did a considerable amount of work on their own account at night, to the detriment of the contractors.

Mr. Trotter, the secretary, pointed out that another section of the Association of Montreal Building and Construction Industries had similar trouble. The section referred to secured the business cards and notepaper of these mushroom firms. A visit was paid to the city assessor, and the firms soon went out of business.

The subject of various stores, outside of the electrical business, including drug stores, was also referred to.

The executive committee will go over the proposed by-laws and report to a special meeting.

Robbins & Myers Expanding

The Robbins & Myers Company, Springfield, Ohio, have just acquired five and one-half acres of ground and all the factory buildings of the James Leffel Water Wheel Company, which adjoins their plant. This, together with the buildings already occupied by the Robbins & Myers Company, give them a continuous floor space of about 500,000 square feet and about fourteen acres of ground. The company will take possession of the new plant as soon as possible and will increase their working force from about 3,000 to over 5,000. This, it is said, will make them the largest exclusive electric fan and motor manufacturers in the world. The company commenced in a small casting foundry shop in 1878, under the ownership of Chandler Robbins and James A. Myers. In 1867 Mr. C. F. McGilvray, who is now president, joined the firm as superintendent. In 1896, with about 200 employees, they entered the electrical field, manufacturing ceiling, desk and bracket fans. In 1899 they built their first power motors. The year following James A. Myers, H. E. Myers and C. F. McGilvray purchased the interests of Chandler Robbins and continued the firm as the Robbins & Myers Company. The purchase from John W. Bookwalter of the old rake factory in 1899 formed the nucleus for the present R. & M. main plant, which was reconstructed in 1907. The complete destruction of the R. & M. foundry in 1914 resulted in erection of Plant Two the following year. Plant Three in the Shuey building was acquired in 1918, and the new warehouse was also built last year. With the retirement in 1915 of H. E. Myers, the official personnel of the company became C. F. McGilvray, president; Wilbur J. Myers, vice-president; and Warren A. Myers, secretary. In 1917 H. E. Freeman joined the company as treasurer.

The Bell Telephone Co. will issue \$4,500,000 of new capital stock, raising the capital to \$22,500,000. The issue is at par, with each shareholder entitled to subscribe for one new share for every four now held.

A Gasoline Waterworks Standby

A neat installation at Lindsay, Ont., is shown in the illustration. It represents a Sterling engine, manufactured by the Sterling Engine Company, of Buffalo, acting as a standby to the motor driven pump. The engine is gasoline driven and in case of failure of the hydro lines, may be started immediately and operated indefinitely. The company state that there are today numerous units of this engine installed in townships, villages and factories as standby plants for fire protection, driving centrifugal pumps and generators. The engines are equipped with electric starter and generat-

"Sterling" engine operates pump in case of failure of electric power

or, battery driven, and are made in six sizes, varying in horse-power from 12 to 200. The equipment is backed by an organization represented in practically every country on the globe. The marine product has been manufactured for over fourteen years, during which it has been used extensively by the United States and other foreign navies. The racing engine built by this company has held the world's speed record for eight consecutive years. This engine is also used direct connected to generators for isolated plant operation.

Electrically Welded Tank

What is perhaps the first electrically welded tank ever made in Canada has just been completed by the Lincoln Electric Company of Canada, Limited. This tank was made for the Canadian Ice Machine Company, of 3/16 inch plate completely welded throughout. One longitudinal seam runs along the bottom and there is another seam about the middle of the tank. The joints were butt welded. Very little labor was re-

Electrically-welded tank, made by Lincoln Electric Company

quired for the job, the plates being held in place by two helpers while the welder tacked them together at intervals. He was then enabled to complete the tank without any further assistance. The accompanying illustration is a photograph of the tank upon completion.

The city council of Edmonton, Alta., have decided to go ahead with extensions and improvements to the telephone system at a cost of approximately \$300,000.

Economic Handling of Coal

A new type of motor-operated portable conveyor, manufactured by the Portable Machinery Company, Passaic, N.J., is shown in the accompanying illustration. While there are an unlimited number of uses to which this conveyor can be put, it is particularly suitable for the handling of coal or ashes around the power plant. Coal may be unloaded direct from hopper bottom cars into wagons, making unnecessary

This portable conveyor is readily adjustable to all varieties of materials

the use of a pit or overhead track. A distinctive feature of this equipment is the scoop on the feeding end which can be pushed, or completely buried, in the material to be conveyed. This makes it possible to simply scrape the material onto the carrying belt instead of lifting it up by shovelfuls into the feeding hoppers of ordinary conveyors. It is said by makers that, with the "Scoop" conveyor one man can unload coal from hopper bottom cars at the rate of one ton in from three to six minutes.

Menominee Fans

The accompanying illustration shows one of the types of Menominee fans distributed by the Masco Company, Limited, 91 Queen Street East, Toronto. Merchants in all lines are more than ever interested in the electric fan as an aid to customer-comfort. Housekeepers who may in former

years have thought the electric fan a purely commercial necessity, now realize that it fills a long-felt want in the home as well as in the office. This should be the biggest year on record for electric fan sales and every dealer will, of course, profit to the extent that he goes after the business.

Plans now under way for a C. N. R. line through New Westminster, B. C., to a point in South Vancouver call for electric operation.

A Lamp That Clamps Everywhere

The Adjusto-Lite is something quite new in lighting fixtures. It can be clamped firmly to any round or square projecting edge or rod—bed frame, table top, door, piano

frame, automobile step—or can be rested flat on the table or floor. It is thus a general utility fixture. Light can be thrown in any direction desired by means of a hinge in the arm and a swivel in the shade holder. Manufactured by S. W. Farber, Brooklyn, N.Y.

Motor Driven Stucco Machine

A recent development is a motor-driven stucco machine by which the material is applied by projecting it from the machine by centrifugal force set up by the revolving spider blades. This machine is manufactured by the Hodges Stucco Machine Company, Cincinnati, Ohio, who state that by applying the stucco in this manner, a skin, or enamel, is formed, making an outside coating which is impervious to moisture. As an instance of the speed at which the machine works it is said that an operator with a helper to supply the material

can project 350 square feet an hour against hollow tile, brickwork or concrete blocks, and a trifle less against such material as metal or wood lath. The equipment is light in weight, aluminum castings being used for the frame and tool steel for the revolving spider blades and automatic feed. The weight of the motor, therefore, represents the greater part of the total weight of the machine. An auxiliary hopper is provided by which pebbles, crushed granite and similar materials can be effectively thrown into the stucco base.

The International Electric Co., Ltd., Montreal, has been incorporated with a capital of \$75,000, to acquire as a going concern the International Electric Co., Messrs. Philippe DeSerres, Steven Dudemaine, Joseph Augustin Faguy, manufacturing electricians, Leonidas Cote and Wilfrid Boisvert, electricians, all of Montreal, all interested.

Keystone Car Specialties

The illustration herewith shows the "Safety" car lighting fixture made by the Electric Service Supplies Company, Philadelphia, and distributed in Canada by the Lyman Tube & Supply Company, Limited. An electric railway benefits proportionately as its service is improved. Better interior

lighting means increased passenger comfort and, consequently, more passengers carried. The Electric Service Supplies Company manufacture a number of other electric railway specialties, including Faraday high voltage car signal systems, Golden Glow headlights, illuminated destination signs, trolley retrievers, motormen's and conductors' seats, and so on.

Polar Cub Electric Fans

The Polar Cub Model D electric fan has the following selling features which are outlined by the distributors in Canada, the A. C. Gilbert-Menzies Company, Limited, Toronto: two speeds; die cast frame; guard spot welded; fan adjustable to any angle; motor nickel plated; mica filled commutator; easily lubricated; rust proof blades; equipped with 8 foot cord and plug; height 8 inches to top of guard, 6 inches to top of motor; guaranteed for one full season and

packed in individual carton with attractive label. Another larger model, No. 9, is 10½ inches to top of guard and 7½ inches to top of motor, with blade diameter of 9 inches. Attractive window display material is furnished when requested, consisting of window stickers, store cards, folders, lithographed cutouts, and so on. The company state that the demand last year for Polar Cub fans more than exceeded the supply, and that the same is true to date this season.

The Bell Telephone Company will issue new capital stock to the extent of \$4,500,000.

Safety Service Switches

The accompanying illustration shows the Devoe Type "A" externally operated safety service switch manufactured by the Devoe Electric Switch Company, Montreal. Several features in connection with this switch are outlined by the manufacturers. The moving arms are constructed in such a way as to give positive motion to the blades which all enter their contacts at the same time. With this construction there is no danger of a three phase motor running single phase or starting fuses being blown; a slotted screw hole is provided enabling one man to install the box; the

base is of Monson slate; locking device to prevent switch from being closed; blades of 98% pure copper designed to make 90% contact; snap catch with hole for padlock; extra heavy cast iron handle; strong check preventing strain on switch when operating. All Devoe safety switches are examined and labelled under direction of the Hydro-electric Power Commission of Ontario.

In connection with the reconstruction of the plant of the Saguenay Light & Power Co., Ha! Ha! Bay, P.Q., the order for the turbine has been awarded to the S. Morgan Smith Co., York, Pa. The unit is 800 h.p., the wheel being of the single horizontal type, 400 r.p.m., working under a 75 foot head. It is to be direct connected to the generator, and will replace an obsolete turbine. This power, in No. 2 power house, will be in parallel with No. 1 power, and the current will be for use at the mill of Ha! Ha! Bay Sulphite Co. and at the wharf terminals. The order includes a length of steel plate penstock.

Trade Publication

Fans, Blowers and Exhausters—Catalog No. 400, by the Buffalo Forge Company, Buffalo, N.Y. It is pointed out by the company that the greatly increased use of fans in manufacturing and chemical plants for a great variety of purposes, together with the demand for greater efficiency, has led to the development of the new types and improvements illustrated and described in this catalog. The booklet also contains a quantity of data and information of use to all fan users.

The Eden Electric Washer

Wide-awake dealers are coming to realize that the way of the electric clothes washer into the home is greatly facilitated by the ever-increasing use of the smaller appliances. Every time you sell a toaster, an iron or a vacuum cleaner you secure a prospect who may, sooner or later, be inter-

ested in electric washing. Especially now that the hot summer months are upon us any relief from the drudgery of wash-day will instinctively appeal to the housekeeper. The washer illustrated herewith is manufactured by the Great West Electric Company, Limited, Winnipeg, and is called the "Eden." The company state it is a first grade machine assuring good profits for the dealer.

Current News and Notes

Brockville, Ont.

The Brockville Public Utilities Commission are endeavoring to secure the electrification of the Brockville and Westport branch of the Canadian Government railways, about forty-five miles in all and serving a rich farming district.

Bronte, Ont.

A by-law authorizing an expenditure of \$6,000 for the installation of an electric lighting system was recently passed by the ratepayers of Bronte, Ont.

Camrose, Alta.

The ratepayers of Camrose, Alta., will shortly vote on the expenditure of \$17,000 for the purchase of new machinery for the local lighting plant.

Chatham, Ont.

The Ontario Hydro-electric Power Commission has recommended to the city council that they take over the plant of the Chatham Gas Company who generate the power used in that city.

Hamilton, Ont.

The style of Moncur & Cook, electrical dealers, Hamilton, Ont., has been changed to The James Moncur Electrical Company.

Hull, Que.

An increase of three cents an hour and a nine-hour day has been granted to employees of the Hull Electric Railway by a board of conciliation.

Montreal, Que.

The International Electric Company, Montreal, have been granted a charter.

Ottawa, Ont.

The Spardon Electrical Products Company, Limited, Ottawa, Ont., have been granted a Dominion charter.

Parry Sound, Ont.

A by-law authorizing an issue of \$165,000 in 6 per cent. debentures, for extending the municipal hydro-electric plant, was passed by the ratepayers on June 2nd.

Peterboro, Ont.

The city council of Peterboro, Ont., have approved the street railway's request for a straight five-cent fare which will henceforth be charged excepting during the morning and evening rush hours. The company has undertaken to improve the service.

Two new one-man cars have been placed in operation on the Peterboro street railway.

Regina, Sask.

Three hundred old style arc lights in the city of Regina will be changed for 400 c.p. nitrogen lamps.

The Northern Electric Company propose moving their western headquarters from Winnipeg to Regina.

St. Thomas.

The ratepayers of St. Thomas, Ont., have authorized an expenditure of \$45,000 for improvements to the street railway.

Swift Current, Sask.

The power plant at Swift Current, Sask., was destroyed by fire recently. It was a Deisel installation valued at about \$80,000. The engines, it is thought, can be repaired although the rest of the equipment is a total loss.

Thorold, Ont.

The Hydro-electric Power Commission of Ontario are preparing a valuation of the 28 miles of railway in the Windsor, Sarnia, and Ford City district owned by the Detroit United Railways, with a view to purchasing.

Westinghouse Promotions

Mr. N. S. Braden was elected third vice-president at the regular meeting of the board of directors of the Canadian Westinghouse Company, held June 4th, and at the same time Mr. H. M. Bostwick was appointed manager of sales. Mr. Braden, who has been manager of sales since the organization of the company, will in his new office have executive charge of the company's commercial organization. He has just returned from a six weeks trip to the Coast. Mr. Bostwick, who has been in intimate relation with all phases of the sales department and latterly has held the office of assistant manager of sales, will take over the direction of the sales forces and the conduct of the department in all its ordinary activities.

GREATER BUYING POWER

That is what the trade paper represents to the man who is a regular and careful reader of it.

In its editorial columns he finds useful ideas that help him in his business—helps and hints that smooth out many of the rough spots—plans the other fellow has tried and found successful.

The advertising pages are also a source of valuable information. Here he learns what the manufacturer has to offer—how those goods are made—the materials that enter into their manufacture—when salesmen are on the road—special opportunities, etc.

He keeps thoroughly posted on the market, because the trade paper is in close touch with the situation and gives him accurate knowledge of conditions—when and what to buy.

Read your trade paper thoroughly each issue and make a reference file of it. You will often have occasion to refer to it.

THE NATIONAL AUTHORITY FOR TWENTY-FOUR YEARS
THE 1919 EDITION

POCKET SIZE
LEATHER COVER

"STANDARD WIRING"

TELLS YOU HOW

GENERATORS—How to install them, care for them and operate them; all their troubles and how to prevent and cure them; all diagrams showing connections for compound, series and shunt wound machines. How to operate them in parallel or in series. How to protect them and wire them in accordance with the underwriters' requirements.

MOTORS—How to install them, how to protect and operate them. The required amperes, volts or horse power when any two factors are known. How to take care of hot boxes, sparking commutators and other troubles. How to change the direction of rotation when desired. How to start and stop any kind of motor in any class of service. All diagrams of motor wiring. How to find the proper size of wire for any motor for direct current or A. C. single, two or three-phase.

OUTSIDE—Line construction, line wires, service wires, poles and their dimensions and Insulators, guard arms, guy wires. How to install Lightning arrest-

weights, and how to erect and protect them and anchors. Tree wiring, splicing, service and wires. Transformers with diagrams and instructions.

INSIDE WIRING—When and where to run wire. How to find the proper size of wire for current, voltage and drop, either by formula or by the tables of the book. How to wire for two-phase and three-phase with formulae and tables in a simple manner that anyone can understand. How to run wires through partitions and walls and where roundings exist. When and how to use conduit. How to take. The proper way to install Outlet, Junction and Switch boxes. Complete interior conduit. Concealed knob and tube wiring. Electric and combination switches. How to use it. How to

LIGHT AND ILLUMINATION

What is meant by proper and efficient illumination, the latest data on Mazda and other lamps of every candle power and wattage. Direct, indirect and semi-indirect illumination. Where each should be used. Illumination required for various classes of service from show window lighting to public halls and from factories to small residences.

TABLES—Fifty-two tables giving every dimension, carrying capacity, resistance, weight and strength of every size of wire and cable of copper, steel and iron.

All the necessary dimensions, capacities, weights, and other data on conduits, fuses, insulators, lamps, sockets, motor efficiencies, current per horse power of motors. Electrical units and their equivalents. Proper size of wire for all classes of power, light and heating installations. The proper symbols to use to indicate on plans just what is wanted from a motor to a small snap switch with all necessary diagrams.

APPARATUS AND SUPPLIES—A classified list of the leading manufacturers of officially approved wires and wiring devices. Engines, generators, motors, appliances, fixtures, and all supplies necessary for any complete installation from a Central Station to a small cottage.

"IT SETTLES DISPUTES AND, IF REFERRED TO BEFORE WIRING, PREVENTS DISPUTES"

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

Electrical Books—Special Prices

The following Books are Offered Subject to Previous Sale:

- "American Electricians' Handbook, a reference book for practical electrical workers, by Terrell Croft, 712 pages, with over 900 illustrations. Published by McGraw-Hill Book Co. Price \$3.00.
- A Handbook on the Steam Engine, by Herman Haeder. Published in 1914 by Crosby, Lockwood & Son. 522 pages, illustrated. Price \$3.00.
- A Laboratory Manual of Alternating Currents, by John H. Morecroft, E.C. Published in 1912 by Renouf Publishing Company. 248 pages, illustrated. Price \$2.00.
- Baudot Printing Telegraph System, by H. W. Pendry. Published in 1913 by Whittaker & Company. 144 pages, illustrated. Price \$1.00.
- "Central Stations," by Terrell Croft, 1st edition published in 1917, by McGraw-Hill Book Co., Inc. 332 pages, illustrated. Price \$2.50.
- Direct-Acting Steam Pumps, by Frank F. Nickel. Published in 1915 by McGraw-Hill Book Company. 258 pages, illustrated. Price \$3.00.
- Direct Current Machinery, Theory and Operation of, by Cyril M. Jansky, B.S., B.A., 1st edition, just published by McGraw-Hill Co., Inc. 285 pages, illustrated. Price \$2.50.
- Dynamo-Electric Machinery, by Francis B. Crocker, E. M., Ph.D. Published in 1908 by American School of Correspondence. 236 pages, illustrated. Price \$1.00.
- Electric Arcs, by Clement D. Child, Ph.D. Published in 1913 by D. Van Nostrand Company. 194 pages, illustrated. Price \$2.00.
- Electric Car Maintenance, by Walter Jackson. Published in 1914 by McGraw-Hill Book Company. 274 pages, illustrated. Price \$2.00.
- Electric Railway, by A. Morris Buck, M. E. Published in 1915 by McGraw-Hill Book Company, Inc. 390 pages, illustrated. Price \$3.00.
- Electric Railway Engineering, by C. Francis Harding, E. E. Second Edition. Published in 1916 by McGraw-Hill Book Company. 416 pages, illustrated. Price \$3.00.
- "Electric Traction," a treatise on the application of electric power to tramways and railways, by A. T. Dover. Published in 1917 by Whittaker & Co. 661 pages with 518 illustrations and five folding plates. Price \$6.00.
- Electrical Injuries, by C. A. Lauffer, M.D., published in 1912 by John Wiley & Sons. 77 pages. Price 50 cents.
- Electro-Dynamics, by Charles Ashley Carus-Wilson. Published in 1898 by Longmans, Green & Company. 298 pages. Price 50c.
- Elements of The Infinitesimal Calculus, by G. H. Chandler, M.A., Prof. Applied Mathematics, McGill University, 318 pages, cloth bound. Published by John Wiley & Sons, 1907. Price \$1.40.
- Elementary Principles of Illumination and Artificial Lighting, by Arthur Blok, A.M.I.E.E. Published in 1914 by Scott, Greenwood & Son. 235 pages, illustrated. Price \$1.00.
- Elementary Graphic Statics, by John T. Wight. Published in 1913 by Whittaker & Company. 226 pages, illustrated. Price 75c.
- Elementary Magnetism and Electricity, by Cyril M. Jansky, B. S. Published in 1914 by McGraw-Hill Book Company. 212 pages, illustrated. Price \$1.50.
- Examples in Alternating-Currents, (Vol. 1), by F. E. Austin, B.S. Published in 1915. 223 pages, illustrated. Price \$2.00.
- Examples in Magnetism for Students of Physics and Engineering, by Prof. F. E. Austin, B. S. Published in 1916. Price \$1.00.
- First Aid in Case of Electrical Shock, by Dr. John Woodman. Published in 1908 by The New York Edison Company. Illustrated. Price 50 cents.
- "Fuel," by C. F. Herington, recently published by D. Van Nostrand Co. 211 pages, with 84 illustrations. Price \$3.00.
- Handbook of Machine Shop Electricity, by C. E. Clewell. Published in 1916 by McGraw-Hill Book Company. 461 pages, illustrated. Price \$3.00.
- How to Make High-Pressure Transformers, by Professor F. E. Austin. Second edition, just published. 48 pages, illustrated, price 65c.
- International Library of Technology, Vol. 11-B, on Electricity and Magnetism, Electrodynamics, Electrical Resistance and Capacity, The Magnetic Circuit, Electromagnetic Induction, Chemistry and Electro-Chemistry, Primary Batteries, Electrical Measurements, 585 pages, fully illustrated, half Morocco bound. Published by The International Textbook Co., 1905. Price \$3.50.
- International Library of Technology, Volume 14-C on Storage Batteries, Incandescent Lighting, Arc Lighting, Interior Wiring, Modern Electric Lighting Devices, Electric Signs, Electric Heating, 540 pages, fully illustrated, half Morocco bound. Published by The International Textbook Co., 1905. Price \$3.50.
- "Powdered Coal as a Fuel," by C. F. Herington, recently published by D. VanNostrand Co. 211 pages with 84 illustrations. Price \$3.00.
- Practical Electric Illumination, by Terrell Croft, First edition, published by the McGraw-Hill Book Co. 225 pages, illustrated. Price \$2.00.
- Principles of Direct Current Machines, by Alexander S. Langsdorf, M. M. E. Published in 1915 by McGraw-Hill Book Company. 404 pages, illustrated. Price \$3.00.
- Principles of Alternating Current Machinery, by Ralph R. Lawrence. Published in 1916 by McGraw-Hill Book Company. 614 pages, illustrated. Price \$4.50.
- Principles of Electrical Design—D.C. and A.C. Generators, by Alfred Still. Published in 1916 by McGraw-Hill Book Co. 365 pages, illustrated. Price \$3.00.
- Radiodynamics—The Wireless Control of Torpedoes and Other Mechanisms, by B. F. Miessner. Published in 1916 by D. Van Nostrand Company. 206 pages, 112 illustrations. Price \$2.00.

- Wray's Manual of Car Lighting. Published in 1915 by Wray Publishing Company. 340 pages, illustrated. Price \$1.50.

ANNOUNCING

A NEW EMERGENCY POWER PLANT

Medium and high speed Sterling gasoline engines (which have held world's marine records for eight years) have been adapted for driving centrifugal pumps and electric generators. They are being used by many prominent pump manufacturers, coupled to Underwriters' fire pumps, and are installed in townships, villages, municipalities, department stores and manufacturing plants for fire protection. They are also utilized for emergency generator drives. The motors are admirable for either pump or generator operation as they develop rated power at 800, 1,000, 1,200 and 1,400 r.p.m. The construction is in 4, 6 and 8 cylinder units, 10 to 300 h.p.

Numerous units are employed in the United States and Canada. They are equipped for instantaneous starting for any emergency and will always furnish dependable power until the emergency will have passed.

Illustrating Durable Dayton No. 676

Six blade 12 or 16 inch Oscillating Fan, convertible to bracket position.

Durable Dayton Fans are easy to sell and good to sell because of their quality—they mean satisfied customers and repeat orders—Dayton fans are sturdily made, for long, untroubled service. They consume less current and their square-end blades deliver more breeze.

Opportunity to "Cash In"

Demand is for quality now, stronger than ever before—Daytons have held the fan quality leadership for 26 years, the best fan for every purpose.

The line is complete, including electric ceiling, desk, and wall bracket models for alternating and direct current, exhaust fans and water motors. Easily adaptable; all Dayton desk fans can be immediately converted into the wall bracket type.

Durable Dayton dealers are given co-operation; sales helps and advertising that brings in customers and profits.

Eliminate the Waste
of Money on Com-
mutator and Arma-
ture repairs by using
the

"No Spark"

CARBON BRUSHES

A mint of money is wasted every year through the installation and use of brushes of an improper grade. With the correct grade of brush specified the commutator and armature last far longer and repairs are reduced to a minimum.

We will save you a great deal of expense and your engineer much worry by taking the responsibility of selecting the right grade of material. Send for our information sheet to-day.

Write for our latest bulletin.

Electric Fixtures, Supplies and Appliances

347 Yonge Street

TORONTO, ONT.

Use it on both A.C. & D.C. Equipment

The Ideal Resurfacer will produce a smooth running surface on both your commutators and collector rings whether your equipment is large or small.

Instead of turning down commutators on a lathe you can cut down high mica, ridges and bars and smooth out hollow grooves simply by applying the Ideal as illustrated, while machines are under load.

The Ideal is an abrasive block—not a natural stone that is sometimes hard and sometimes soft and that clogs with copper dust, but a specially manufactured product of uniform density and cutting quality throughout. Applied to commutator and collector ring wherever trouble develops it keeps your equipment in perfect running condition.

Ideal Commutator Resurfacers

are used by many of the country's largest industries on varied equipment—proof that satisfactory results are obtained. We list among our customers such concerns as Ford Motor Co., Packard Motor Co., General Electric Co., Armour & Co., Swift & Co., New York Central R.R., Commonwealth Edison Co., etc.

To prove to your own satisfaction that the Ideal is all we claim we want you to try it on your own equipment at our expense. Simply fill out the coupon—you incur no obligation whatever. If after a thorough trial you do not wish to keep it, return it—the trial will not have cost you a cent. Send the coupon now while the matter is in mind.

IDEAL COMMUTATOR DRESSER CO.,
4 So. Dearborn St., Chicago.

Short Circuits

in motors and dynamos are often traced to faulty insulation.

Use a varnish you can trust. "ARMACELL" baking and "OHMALINE" air drying insulating varnish have all the qualities of a perfect insulator; when dry remain perfectly flexible and possess a smooth, bright, water and oil-proof finish.

For
Generators Dynamos Motors
Transformers Accelerators Etc.
"Armacell" and "Ohmaline" are absolutely reliable

Send for interesting booklet on insulating varnishes and protective varnishes.

Why

DENZAR

Gives Perfect Illumination

This new and improved unit provides better light with less current because of these points of superior construction:

- 1—Housing of steel, white porcelain enameled.
- 2—Yoke of spring steel supporting metal holder.
- 3—Metal holder supporting reflecting dome and lower bowl.
- 4—Reflecting dome of opal glass, softens and distributes light.
- 5—Adjustable hanger for adjusting lamp without removing glassware.
- 6—Deflector diverts upward rays downward on to working plane.
- 7—Upper part of bowl, clear glass, protects lamp from dust and dirt.
- 8—Lower part of bowl, white enameled glass, softens and diffuses light.
- 9—Air intake, allows cool air to pass upward continually around lamp.

Dealers have no difficulty in building up a large and highly profitable business on DENZAR.

Write for the DENZAR catalog, showing different types, sizes and prices.

Walger 3-Way Connection

Your Kit Bag is Not Complete Without Them

The Walger way will make your connection in one-fifth the time and give a neater, cleaner and more satisfactory job. Walger Connectors are the only solution for fixture installation, they are a great help when making connections in awkward and inaccessible positions. Approved by the Underwriters' Laboratories, Chicago, and Hydro-Electric Power Commission of Ontario for No. 12 Wire and under. Don't be without this important help to your work.

BRADSTREET'S
Offices Throughout the Civilized
World.
Executive Office:
Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a Specialist in Repairs. Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an absolutely reliable job. You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine (Profit). Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the Trade Discount (More Profit).

Others are doing it. Why not you? Write about it.

ECONOMY

Renewable FUSES

stand between the user and unnecessary expense. An inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency. The resultant saving approximates 80% of annual fuse maintenance costs as compared with the use of one-time fuses.

This economy is effected with safety, as years of use have conclusively proved that Economy Fuses are all that could be desired as regards accuracy of rating and all round efficiency. They cost least and serve best.

If you are among the thousands of Economy users you already know this. If not, try them and you *will* know.

Sold by leading jobbers and dealers everywhere.

Best Known Cable

Reel In Canada

THE demand for Northern Electric products and the fact that they are made by the largest manufacturers of bare and insulated wires and cables for electrical distribution is a positive assurance of quality.

They are as near perfection in both dependability and durability as experience, workmanship and superior materials, combined with the most modern machinery, can make them.

Bare copper, rubber covered and paper insulated, lead covered cables of Northern Electric manufacture—are designed by the most capable engineering skill and tested to ensure safety and efficiency to the fullest degree possible.

Our nearest House will be pleased to submit specifications and prices upon request.

RAILWAY HEADLIGHTS

No Kick-Back---

"Golden Glow" Headlights project a soft, penetrating light which is very nearly the color of molten gold. This "Golden Glow" light is a real friend to motormen, because it does not "kick-back" into their eyes when used in foggy, rainy or snowy weather, to such an extent as a white light.

You can readily appreciate their reason for favoring "Golden Glow" light in preference to a white brilliant light, if you will make a test in stormy weather of both qualities of light. You'll then see how "Golden Glow" light penetrates without the blinding "kick-back."

It's the reflector in "Golden Glow" Headlights which does the trick.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance.
Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is \$66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

The Switch You Have Been Looking For

Single Pole of 3300 Type
80000 volt Pole Top Dis-
connecting Switch. This
type is ordinarily supplied
as a two or three pole
outfit and so constructed
that all poles are operated
by one mechanism.

Here it is! A great
big rugged fellow!

You have been having trouble
with your out-door switching
equipment; take a look at this
illustration.

Our 3300 Type Switch, as
shown, is made for all voltages
7500 to 80000; it has double
break per pole, arcing horns for
opening underload, long bear-
ings, insuring smooth and easy
operation, sleet hoods and many
other excellent features. Let us
tell you more about it in our
new bulletins.

WITH no danger sign to warn you when a breakdown is coming your way, you have the more reason to be on your guard—to “stop, look and listen,” and especially “look.”

Look now to the strength and condition of your equipment, and bear in mind as you look that every “FRANKLIN” Device you install crosses one more “worry-point” off the list. Whether for replacements or in extension work, “install the ‘FRANKLIN’ and forget it.”

In “FRANKLIN” Post Type Insulators, metal bushings moulded to the porcelain do away with clamped or cemented fittings. By the even distribution of strains brought about by the intimate contact of these bushings with every point of the porcelain’s circumference, the carrying capacity of the insulators is greatly increased, and the likelihood of breakdown reduced to the minimum. This distinctive and important feature is supported by marked general superiority in design and structure.

In addition to Post Type Insulators, “FRANKLIN” Specialties for Generating Stations comprise Disconnecting Switches, Potheads, Doors for Bus and Switch Compartments, Instrument Cutout Switches, Cleat Type Insulators, Air Pressure Relays, and the new “FRANKLIN” Fuse. Write for descriptive Bulletins.

Watthour
Meter**

Accessibility

All parts of C G E alternating current watthour meters are readily accessible. For full load and light load adjustments, inspection of the register, disk and magnets, the removal of the meter cover only is necessary. The electrical element is readily inspected or removed by taking off a cover plate on the back of the meter. Placed over the terminals is a cover permitting access to the terminal compartment and supporting screws, without giving access to the meter proper.

The accessibility of C G E alternating current watthour meters, is a feature as distinctive as their recognized accuracy.

A War Created Opportunity For The Dealer and Central Station

Individual electric motor drive, because of its convenience and safety, was one of the important factors which made it possible for women workers to relieve men on machine work during the war.

This condition together with the demonstrated reliability of R & M Motors and Central Station service, has converted many power users to the permanent employment of the Central Station Service-Robbins & Myers Motor Combination.

Central Stations, Contractors and Dealers in R & M Motors find users of this combination permanent customers, and the kind whose good will helps in getting business from other prospective customers.

R & M reliability is a sales asset which all distributors of electric motors and electric service can tie up to with profit.

No. 13

The Electric Industry Weak in the Selling End

At the recent Niagara Falls convention of Ontario municipal engineers, Mr. Goodwin emphasized again and again that "The great problem of the electrical industry of the future is the commercial problem." The engineering problems are being taken care of satisfactorily, the manufacturing problems, the supply and distribution of current, but when it comes to the selling end as regards appliances and devices generally used by the consuming public, the industry is weak.

This fact must now be recognized by anyone who has studied the situation at all closely. Electrical merchants, as a class, do not exist. There is nothing in our industry that corresponds to the retailers in the shoe industry, or the grocer, the hardware store or the druggist, each of which is an old established "custom," so to speak. The people look upon these stores as necessities and the fact of this long existence has created a class of men who are skilled in handling this retail business. In the electrical retail trade there has been no time to train salesmen and the public have not yet come to look upon electrical appliances except as luxuries.

Here then is the problem of the industry—of the manufacturer, the jobber and the central station. An electrical merchant class must be built up. It is useless to hope that this class will spring into existence of its own accord. Even

if it would, the process would take years and in the meantime the industry—and the public—would suffer.

Having admitted then that the problem of the industry is the commercial problem, that more electrical goods must be sold, many times more; we find ourselves face to face with the problem—how? There is the real problem. How can we establish electrical stores? How can we equip these stores with efficient salesmen who understand merchandising? Who is going to accept the responsibility?

Standard of C.M.A. Officers Temporarily at Low Ebb

The general public, having become accustomed in past years to respect the utterances of the Canadian Manufacturers' Association as the result of the prominent connection with this association of such names as Senator Frederic Nicholls, Mr. W. K. McNaught, C.M.G., Mr. W. H. Rowley, Hon. Nathaniel Currie, Sir Chas. Gordon, Mr. Lloyd Harris, Mr. Robert Hobson, Hon. C. C. Ballantyne and others scarcely less prominent industrial figures, must have noted with considerable disappointment the recent explosion of one of the members at the annual convention, in which he made use of language not generally accepted, to say the least, as forming part of a gentleman's vocabulary. That the president of the association, Mr. W. J. Bulman, an insignificant Winnipeg manufacturer, sat quietly by and allowed the members to proceed, makes him equally responsible. The incident doubtless is without significance in itself beyond the fact that it indicates that the standard of C.M.A. officials is, temporarily we hope, at a very low ebb.

The Canadian Manufacturers' Association is an organization on whose shoulders grave responsibilities regarding the industrial development of our country rest. We do not believe the members of that association, even a small fraction of them, are favorable to the use of such unbridled and offensive utterances as those made by this Mr. Harris on the occasion referred to. If the Canadian Manufacturers' Association is to become an arena for such disgraceful brawls as the recent demonstration of this man's boorishness, the influence of the organization cannot fail to deteriorate very rapidly from the high standard of past years.

Definite Policy on Naval Defence is Suggested

The proposed visit of Admiral Lord Jellicoe to this country is made the occasion of a strong plea in the June issue of "The Sailor" for a definite policy on naval defence and, as a basis of argument, the following policy is suggested:

That Canada and the other Dominions should take over the responsibility of protecting trade and sea communications of the Empire in time of war and subordinate their naval programmes to that function entirely; and that Great Britain should retain the responsibility of maintaining the battle-fleet, with its proper accompaniment of cruisers, etc., necessary to uphold whatever world policy the Empire decides is proper.

The article states that this policy, like all other policies, is open to certain objections, but it is believed that the advantages more than outweigh the criticisms that can be made against it. These advantages are summed up somewhat as follows:

1. The purely defensive characteristics of the arrangement. It cannot be contended that such a policy is militaristic or aggressive in design. It has been clearly stated in the words of the most responsible advocates of the League of Nations that such an instrument cannot be expected to end all wars, consequently, if the Empire is to exist, proper defence measures **must** be taken, that is, if we are to be at the same time worthy heirs to the heroes who built and left

us our precious heritage, and unimpeachable trustees for our successors.

2. The inter-dependence which such an arrangement involves between the component parts of the Empire will form a material bond far stronger than sentiment and Imperialistic speeches. Co-ordinated action in the matter of defence will do more than anything else to counteract the centrifugal tendencies of peace conditions, which are perhaps as much, or even more, due to the insidious propaganda of outside parties interested in the disruption of the Empire, than to any really conflicting interests born of trade rivalries or national aspirations.

3. The ease with which the machinery for defence can be manipulated in case of war or emergency, when each unit has its allotted task beforehand, instead of having to compromise between the conflicting requirements of Maritime defence.

4. The independence of action of each Dominion Navy under its own administrative heads, thus relieving the Admiralty of one of its most serious responsibilities. Interchange of individual vessels or of divisions, throughout the Empire in peace time is advocated in order to encourage uniformity of system and mutual understanding.

5. Economy in expenditure owing to concentration of effort, also greater efficiency resulting from concentrated study on particular spheres of Naval action and consequent expert knowledge.

6. And by no means least, the moral effect in time of peace of showing the flag of the Empire in all the waters of the globe co-operating in an organized system of defence.

Causes of Accidents

The 1918 report of the Workmen's Compensation Board of the province of Ontario has just been issued and shows, under the heading "Causes of Accidents, 1917," that "electric currents" were responsible for 81 cases, including medical aid, compensation, permanent disability and death. The total of all other classes of accident was 25,265. The report points out that primary causes of accident alone are possible of tabulation; secondary causes, such as bad lighting and so on, are not susceptible to tabulation, unfortunately, for they are often the train of circumstances leading up to the actual accident and are of greater importance from a prevention point of view than the primary cause itself. The Board also state that the employer's responsibility in cases of non-mechanical accidents is perhaps greater than he is willing to admit and even greater than he thinks it is. If a workman slips and falls it seems hard to charge the employer as responsible, but the condition of lighting might be directly responsible for the accident. The Bulletin of the Industrial Commission of Wisconsin is quoted as follows: "The statement has been made numerous times that of 500,000 avoidable accidents annually, 125,000 may be attributed directly or indirectly to poor lighting. While definite statistical proof of this statement is lacking, it is believed to be a conservative estimate."

Victory Year—Canadian National Exhibition

This year will be Victory year at the annual Canadian National Exhibition, to be held in Toronto, August 23 to September 6 inclusive, and, even though during the war this big event continued to grow better and brighter each year, the present year is certain to eclipse anything that has gone before. The confidence inspired by our success in the war, together with the signing of peace which will almost be a matter of history by that time, makes this prediction conservative.

The advance lithographed hanger, which is just being distributed, is one of the most attractive ever issued by the C. N. E. management. The prevailing colors are red, white and blue. Miss Canada is shown astride a powerful horse, holding aloft the Union Jack, and, standing beside her, a stalwart, khaki-clad Canadian soldier.

The exhibition will be opened by H.R.H. the Prince of

Wales, and, among the many attractions, the following are noted: Grenadier Guards Band; Surrendered German U-boat; Canada's Official War Trophies; Canadian War Memorial Paintings; Mammoth Live Stock Show; Tractors; Acres of Manufacturers' Exhibits; Government Exhibits and demonstrations; Four Days of Motor Boat Racing, with Mile-a-Minute Boats; Poultry, Dog and Cat Shows; International Photographic Salon. The Grandstand performance will be called "The Festival of Triumph" and will, it is said, be the most gorgeous spectacle ever produced. Scores of other attractions will help to make Victory Year a record-breaker.

Must Have Provincial Charter

It has been debated in various provinces in Canada whether a company operating under a Dominion charter could be required by law to take out a provincial charter. The Supreme Court of Canada has handed down a judgment deciding in favor of the provinces, which means that a Dominion company can be compelled to bring itself under a provincial companies' act as a condition of carrying on business in the province. The effect of the decision appears to be to make a Dominion charter valueless for practical purposes in those provinces which require such companies to take out a provincial license. The decision would appear to apply to all classes of Dominion companies, including insurance companies. The provinces requiring provincial licensing are Ontario, Manitoba, Saskatchewan, British Columbia and New Brunswick.

National Electrical Code Correction

In the 1915 edition of the National Electrical Code the second paragraph of Rule 23, section "a" read as follows:

"Where the switch required by No. 24 'a' is inside the building, the cutout required by this section must be placed so as to protect it, unless the switch is of the knife blade type and is enclosed in an approved box or cabinet, under which conditions the switch may be placed between the source of the supply and the cutout."

Through an error this section was omitted when the 1918 edition was printed.

The Electrical Committee of the National Fire Protection Association has voted that this matter be given the widest publicity, that all interested parties may be advised that this section was omitted. The Electrical Committee would recommend that Inspection departments approve an installation in accordance with this paragraph.

Canadians at N.E.L.A. Convention

A number of Canadians attended the recent convention of the National Electric Light Association including Arthur Doddridge, Quebec Electric Company; F. G. Clarke, Toronto Power Company; R. S. Kelsch, Montreal; Geo. D. Leacock, Moloney Electric Company; L. G. Ireland, Ontario Hydro Commission; C. C. Bothwell, Canadian Laco-Philips Company; A. A. Dion, Ottawa Electric Company; Wills MacLachlan, Toronto and D. H. McDougall, manager Toronto Electric Light Company.

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

Municipal Electrical Engineers Hold Successful Convention

Characteristic Addresses by Mr. A. Monro Grier, K. C., Mr. W. L. Goodwin and Mr. Samuel Chase—Papers Presented by Mr. R. C. McCollum and Mr. C. E. Schwenger—Name Changed to "Association of Municipal Electrical Utilities"

The Association of Municipal Electrical Engineers held another successful convention at the Clifton House, Niagara Falls, on June 19, 20 and 21. The program, as previously announced, was followed according to schedule, largely due to the fact that precautions had been taken to prevent overcrowding. The convention proper consisted of interesting papers by Mr. R. C. McCollum and Mr. C. E. Schwenger, and addresses by Mr. A. Monro Grier, K. C., Mr. W. L. Goodwin and Mr. Samuel A. Chase. The greater part of the first day, however, was taken up with a discussion of certain changes in the Constitution and with the presentation of committee reports.

It was decided to change the name of the organization to "The Association of Municipal Electrical Utilities."

Report of Committee on "Bare vs. Weatherproof Covered Wires, for Potentials Above 750 Volts"

You will remember that at the January meeting of this Association, the excellent paper by Mr. A. S. L. Barnes on the above subject, provided a very interesting and profitable discussion. Owing to the somewhat limited amount of time then available and with a view to bringing out additional information, it was felt that the practical side of the question should receive still more attention and discussion. A committee was therefore appointed by ex-president Buchanan for the purpose of obtaining the opinions of experienced outside construction and maintenance men, as to the relative merits of the "Bare vs. Weatherproof Covered Wire," for potentials above 750 volts. The committee appointed consisted of John H. Heeg, Guelph; T. E. Bell, Mimico; C. W. Alford, London; J. W. Cook, New Toronto, and the writer.

As it was desirable to reach as many as possible of these qualified to express an opinion, it was decided that a circular letter, with a question form, was the best method of obtaining the desired results. The questions submitted were as follows:—

(1) Considered from the standpoint of safety to life, is weatherproof line wire safer than bare wire for general distribution on voltages over 750;

(2) If so, at what voltage is a covering of no value?

(3) Is weatherproof wire any advantage from an operating standpoint, as regards crosses, grounds, or freedom from foreign wire troubles?

(4) Are you in favor of it being abolished entirely for line work for voltages over 750?

As "Safety to life" and "Continuity of service," are possibly the two most important factors from a practical man's standpoint, the question, you will notice, covered these points only.

In all, 128 inquiries were sent out and a total of 65 answers received. The replies have been tabulated as follows: From hydro municipalities, 45; from other municipalities, 9; other public service corporations, 11.

(1) In favor of weatherproof insulation from safety to

life standpoint—Hydro, 39; Municipal, 5; Company, 11; total, 55, out of 65.

Not in favor of weatherproof:—Hydro, 6; municipal, 4; total, 10; out of 65.

(2) Voltage limit for weatherproof—750 volt, 7; 1100 volt, 36; 2200 volt, 21; 4400 volt, 17; total, 48.

(3) Advantage of weatherproof from operating standpoint—covered by question No. 1.

(4) In favor of abolishing weatherproof for voltages over 750, 10.

It will be noticed that of the eleven companies that have reported, none are in favor of the bare.

Many instances were cited in replies received of the value of the covered, as against the bare wire, and also several suggestions that weatherproof insulation be improved in quality and durability, but time and space will not permit of taking up these matters at this time.

In conclusion, it would seem that weatherproof covering for voltages over 750 is still in greater favor than the bare with men responsible for the construction and maintenance of overhead distribution systems in municipalities other than rural.

(Signed)

R. H. Martindale.

Inspection Fees too High

Following a discussion of the inspection fees charged by the government, the following resolution, moved by Mr. McHenry, seconded by Mr. Buchanan, carried:

"That, whereas the Inspection Act under Clause 27 in regard to the regulation of fees for the testing of electrical meters states that such fees shall be so apportioned that they will as nearly as possible meet the actual cost of effectually carrying on such inspection.

And, whereas the report of the Inland Revenue Department shows that in the past nine years there is a net surplus from inspection of electric meters amounting to \$238,773.29.

And, whereas the rates now in force were designed some years ago, when conditions were vastly different from those existing at present, and as there will be an ever-increasing use of electric meters with consequent re-inspection of same,

Therefore, be it resolved that in the opinion of the Association of Municipal Electrical Utilities of Ontario the present inspection fees are much too high, and this Association therefore petitions the Department of Trade and Commerce to give the question of reduction in the rates for electrical meter inspection, serious consideration, and to effect such reduction in keeping with the intent of the Inspection Act.

Display of Labor-Saving Devices

An interesting feature of the convention this year was the manufacturers' exhibit. The display of labor-saving devices was particularly appropriate in view of the prevailing hot weather during June this year, consisting as it did, of all those household devices which make for comfort and

efficiency. Among the exhibitors were: Canadian General Electric Company; Canadian Westinghouse Company; Acme Stamping & Tool Works; Canadian Porcelain Company; Hoover Suction Sweeper Company; Hughes Electric Heating Company; Hurley Machine Company; Jefferson Glass Company; Lowe-Martin, Limited; Majestic Electric Company; the McClary Company; Moffat Stove Company; National Electric Heating Company; 1900 Washer Company; Northern Electric Company; Packard Electric Company; Renfrew Electric Company, and Sangamo Electric Company of Canada.

The Convention Dinner

The dinner on Thursday evening was a most enjoyable affair and the all-too-brief address of Mr. A. Monro Grier, K.C., gave the delegates one of the most delightful hours of the convention. The speaker announced his pleasure at being present at the banquet as the guest of the municipal engineers, expressed his feeling of good will and good fellowship towards any body of men associated with the industry in which he himself was so vitally interested and, as

one who had been associated for many years with the greater development of Niagara power for the use of the province of Ontario, welcomed them to Niagara Falls. His address will be given in greater detail in a later issue.

The Goodwin Plan

On Friday morning Mr. Chase and Mr. Goodwin both addressed the convention. Mr. Chase urged the adoption of his slogan: "Live and Help Live," as a more modern interpretation of the attitude of mind of capital and employer towards employees and customers. Mr. Goodwin covered much of the old ground and opened up to his hearers a vision of a better era in electrical merchandising when the various sections of the industry—manufacturer, jobber, central station and contractor-dealer—shall have merged their identities into one vast force working for the good of the consumer through the more intensive cultivation of the field for labor-saving devices. Mr. Goodwin, always a forceful and convincing speaker, excelled himself on this occasion. In our next issue a fuller report of the addresses of both Mr. Chase and Mr. Goodwin will be printed.

Routine Handling of Consumers' Accounts

By Mr. R. C. McCollum*

In planning a system for handling consumers' accounts of a Hydro Electric Utility, there are several principles of so outstanding a nature that they must be recognized and the system built around them. Briefly, they might be given the following relative importance:—

- 1st.—The record should be concise, but in sufficient detail that any error in the monthly bill can be promptly detected, or any complaint of a customer can be intelligently discussed without going back to the meter card or any other record.
- 2nd.—It should occupy the minimum office space and in its operation be as noiseless as possible.
- 3rd.—It should be accessible to any number of clerks at the same time.
- 4th.—The index should be rapid and definite and should provide for unlimited expansion.
- 5th.—It is especially desirable that when used in Hydro offices where a uniform system of rates is in force throughout the Province, the forms should be uniform, to secure the greatest measure of economy in installation and renewals.
- 6th.—It should be possible to examine the charges for any particular class of service without disturbing the balance of the accounts.
- 7th.—The records should be so kept that representatives of the Hydro Electric Power Commission can, in the minimum time, extract from them such information as is necessary from time to time, to check the actual working out of rates and modifications of same as is required by the provisions of the Power Commission Act.

A careful survey of the situation and a study of the practice of public service corporations here and in the United States lead to the selection of a card system as most nearly measuring up to the requirements and so far as I know there are but three Hydro municipalities in the Province of Ontario, where the card system has not been adopted. This does not include municipalities connected to the Central Ontario system in most of which registers are still in use.

The adaptability of card records to the requirements generally, will be admitted by all who have used them. Under

the old system of rates, consisting of a straight kw.h. charge with possibly a fixed meter rental, the old fashioned register, though clumsy, answered the purpose. It required the exclusive use of a large desk and could be worked on by but one clerk at a time. If, as was usually the case, every alternate line was left blank to accommodate new accounts, the register was extravagant in the use of paper and the number of leaves which had to be turned in posting. It also had to be re-written each year, a task looked forward to with dread from about vacation time. As a rule all the information it contained was the gross and net charge, and date of payment, and the only way the billing and extension could be audited, was by checking back to the meter records something that in practice was rarely if ever done.

Card Ledger Gives Much Information

A card ledger, properly kept, can be made to give an amazing amount of information. The color scheme generally used, shows readily the number of domestic light, commercial light and power services. By the use of an offset or a tumble card, the daily postings, both debits and credits, can be check posted, and, where a control account is kept, the office can be closed each night with that satisfaction, so dear to every real bookkeeper, of knowing that his accounts are in balance. Where the cash is check posted to the cards, as is usually done, without the use of a control account, these tumble cards can be used to indicate debit balances, so that a manager can run his eye over his card trays any day in the month and pick out every account in arrears, without examining or even touching another card in the tray.

The average manager of a Hydro system will admit that the matter of arrears is about the least of his troubles. It is not at all unusual for records to show not over two or three per cent of accounts in arrears,—and I have one municipality in mind where for three consecutive years the books have been closed without a single account in default. Such conditions could never obtain where managers had to pore through hundreds of pages of ledger or register to draw off delinquent lists.

It is the universal practice in even the smallest municipalities to keep the consumers' accounts in meter reading route order. The advantages of this are too obvious to

*Auditor Municipal Accounts, Hydro-Electric Power Commission of Ontario.

need explanation, but there is much difference of opinion as to just how far this system should be elaborated.

With the exception of a few of the very largest municipalities, it was the practice, until quite recently, to send the months' bills out at one time, approximately the first of the month, with a uniform discount date thus crowding into about fifteen feverish days the work that should have been spread over the entire month. About the only advantage of this plan was the impression which was conveyed to the citizens who usually called at the office each month on "fever" day to pay their bills, that it was the busiest and best organized office in the town, an impression usually very far from the truth. It is with these two phases of office routine that I wish to deal.

Continuous Billing in Larger Municipalities

In all municipalities large enough to require the services of a meter reader for over six days a month, continuous billing should be inaugurated, and an arrangement of cards and numbering adopted to facilitate this plan.

Where the meters can be read by one man in less than a week, a fixed billing and discount date is probably the best plan. All that is necessary is to make out a meter card for each consumer and have the meter reader, assisted by someone who knows the town thoroughly, number the cards from one up, in the order in which they will ordinarily be reached, leaving blanks for vacant or unwired houses, vacant lots, or any district where additional accounts are likely to develop. Another plan is to leave every second or third number blank, according to the district, alternating from odd to even numbers, so as to use approximately the same number of cards of each tab. Either of these plans will work satisfactorily, if plenty of blanks are left, and blank numbers cost nothing. Our experience has been that when the cards are rewritten at the end of two years, the re-numbering at that time is practically permanent. A large number of excess blanks is preferable to the use of fractional numbers or an initial affix.

In larger municipalities where continuous billing is advisable, the area should be divided into from ten to twenty-five districts, according to the size of the city. This can best be done by marking off on a large scale map, in colored ink the districts decided on. This should be very carefully done, commencing in the centre of the city and working out, making each district small enough that the meter reader ordinarily can cover it in three-quarters of his working day, leaving a comfortable margin to take care of pickups, re-check apparent errors, and catch up delays due to holidays, sickness or accident.

Where it is proposed to have the meter reader deliver the bills, and the districts are made small enough to be read in the forenoon, it is quite practicable to have the bills delivered in each district on the afternoon of the day following the reading, and the pickups taken care of at the same time.

With the possible exception of the main business streets or where for lack of paving the meter readers are unable at certain seasons of the year to cross at will, it will be found best to draw the district lines on the map so as clearly to include or exclude the street. There need, of course, be no outside limit to the last row of districts which extend to the present city limits.

On the map, each district should be numbered boldly in the centre. Each street in each district should be given a sub-number, commencing at No. 1, as nearly as possible in the order in which the meter reader will reach them. No attempt should be made to give one street the same number in two or more districts unless the numbers fall naturally.

With the aid of a city directory you can now, if desired,

mark on the map the house numbers at the district intersection of each street, or this information can be placed in a small card index in the following form for each street and filed alphabetically:

Queen Street	District	Street
1—137	1	1
139—230	3	2
231—End	7	4

As each consumer is given a permanent number consisting of his district, street and house number, when Mr. Smith signs an application and contract and gives his address as 87 Queen Street, you immediately register his contract and ledger card 1-1-87 with no fear of duplication or conflicting numbers. Of course the number belongs to the house or service and will pass to Mr. Smith's successor if he should vacate.

The contracts are naturally filed alphabetically and afford a perfect index to the ledger account at all times, but in actual practice it will be found that the customer who mislays or forgets his bill can usually remember where he lives and with this information the clerk can find his ledger card in the tray in less time than the contract or index card in the alphabetical tray can be located.

This system is permanent and perpetual, and allows of unlimited expansion. The only difficulty to be encountered is business blocks and apartment houses, which if small,

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

can be keyed alphabetically, or if large, can be given a number same as a street, which is practically what they are.

An Uncertain System

Of course there are other ways of securing meter readings. I recall our first visit to a large Hydro city where they were getting along without any meter cards. The consumers' accounts were kept in loose leaf ledgers, one name to a sheet, and they well nigh filled a room. Each day a clerk went through a section of these ledgers and wrote on little slips about three inches square the name and address of the consumers whose meters were due for reading, and these slips were handed to the meter readers. The next morning the meter readers turned in all the slips which they hadn't lost, with the readings, and it was the duty of the office boy to put these slips back in the ledgers beside the customers' account, leaving one end protruding as a marker. Then the billing clerks made out bills for all the accounts so marked, and charged the ledger account accordingly. If the office boy lost the slip, or shoved it in too far, or if it fell out, or if the meter was in the attic, or the customer kept a cross dog,—no bill went out for another month. Hundreds of customers were not billed for periods running from six months to a year, and as with such a system no follow-up scheme was possible, the ledgers contained literally thousands of dollars worth of bad accounts which were finally written off as uncollectable.

Various styles of billing forms are in use, the size and form varying according to the personal preference of local officials. A standard form is stocked by the commission and is used generally by the smaller municipalities, but in towns and cities the bills should of course be printed locally, and should carry the address and office hours. Where

the bills are sent out at one time, a vast amount of writing can be saved by having the printer set in the date and discount period, changing the month when approximately a month's supply is run off. A few extra bills left over each month is a small matter, and a shortage can be made up from extra blanks, and in addition to the saving in writing, the bills present a neat and businesslike appearance. In some offices it is the practice to alternate the colors each month, a plan which does not cost anything and very frequently prevents the inadvertent allowance of discount on a last month's bill.

In all offices where there are one thousand or more customers the bills should be numbered and addressed with an addressograph or some similar device.

With such a machine a clerk in a few hours will do with neatness and accuracy work that would otherwise require days of laborious copying.

The fact that bills are headed for every account is a constant check against record cards being out of the cabinet, and insures against errors in address. Where bills are sent through the mails, the address should be so placed that window envelopes can be used. A perforated envelope costs about half as much as one with a transparency, and is much more efficient.

Stub and Bill in One Operation

When addressing machines were first introduced, the saving in time and labor was so great that it was considered no hardship to make the same impression on both the bill and stub,—but we now find that by placing the account number at the right of the address, so that it will fall on the stub, and the name and address on the body of the bill, a single impression is all that is necessary, thus affecting a further saving in this work of approximately 30 per cent.

Bills with perforated stubs should be so prepared that the figures on the stub will be placed on the extreme left, immediately adjoining those on the bill itself, so that both sets of figures are visible without changing the focus of the eye. This will practically eliminate transposition of figures, and ensure the stub carrying the same figures as the bill. Errors in stubs have caused many an hour's work with a cash drawer that would not balance.

It is generally admitted that a running detailed record of cash receipts should be kept in every well organized office, although in many offices the stubs are simply run through an adding machine after posting, and filed with the listing slips wrapped around them. I have had considerable experience balancing ledgers where this practice was followed; and where so many bills are for the same amount the slips are of no use in checking, even when they can be found. I consider the practice slovenly and altogether undesirable. The daily listing of the stubs in a cash book, using the account numbers instead of the names, is not a formidable undertaking and leaves a record for the municipal auditor of which the manager need not be ashamed.

By using a split adding machine, the cash book may be

entirely prepared mechanically and added at the same time. A single split will give all the information necessary, even where a complex account number is used, by placing the district number at the head of each list on the non-add side. Such cash books are in use in a large number of municipalities and are giving general satisfaction, affording a neat, concise record in a very limited space.

In one police village an enthusiastic trustee undertook to do all the clerical work himself, and when we called at the end of the year to close the books, we were handed the meter book and the pass book. In this case it was actually necessary to call on every customer in the village and examine their receipted bills in order to secure data on which to build up a cash book.

The foregoing outlines the plan of handling consumers' accounts which in whole or in part is in use in every Hydro municipality in Ontario. In general efficiency I feel it is the equal of any system in general use, and that the average cost is at least fifty per cent. less than that of public service utilities using cumbersome ledgers or registers and passing the charges and collections through a control account which, in many cases, is thousands of dollars out of balance, and where, after the adoption of continuous billing, the proof of balance is practically impossible. I have in mind two Hydro municipalities where the accounts were regularly audited by chartered accountants of recognized standing, but who made no effort to justify the control account although in one case it was known to be over three thousand dollars out of balance—also another city where the five billing districts were handled through five separate control accounts, and where one clerk was assigned exclusively to keeping these accounts straight although there was practically no possibility of any actual shortage in the cash which such a check could detect as the collections were made in another office,—and of still another case where an auditor was paid a special fee of \$2,200.00 to re-check his previous work and locate discrepancies in the control account amounting to \$3,500.00, although in this case also there was no thought of locating any missing cash or increasing the revenue.

It seems a far cry back to the early days of Hydro when one manager made his collections personally, entering them in a loose leaf pocket memo which he destroyed as soon as the items were posted in his ledger. It was the most satisfactory customers' ledger I ever saw, as every account was kept balanced by the simple expedient of never making any charges until the collection was entered. As it was a flat rate town with no meters, and the manager varied his charges from month to month according to the amount he thought they ought to pay, there wasn't much work for the auditor unless something had destroyed his faith in his fellowman. I also recall two other municipalities where the secretary kept an ordinary receipt book on his desk, and carefully filled one out for each customer, completing the stub for his own record.

Operation of Overhead Distribution Systems

By Mr. C. E. Schwenger*

In this paper attention will be called to some of the more important details entering into the design and operation of overhead alternating current distribution systems, touching upon certain points with a view to bringing about a discussion which may result in arriving at conclusions of mutual benefit.

These will be brought forward under the following general headings:

- (a). Secondary Lines.
- (b). Transformers.
- (c). Primary Lines.

Secondary Lines

Under secondary lines will be included all lines intended to supply service direct to apparatus on consumers' premises at voltage of 600 or less. Such apparatus includes motors, lighting and heating equipment.

For the purpose of this paper we shall consider parti-

*Engineer of Distribution, Toronto Hydro-Electric System.

(1) Evenly distributed secondary, Browning Ave., East of Arundel; (2) 2200 volt cable on trees, Jarvis St., south of Bloor; (3) Bank of 3-200's on 4100, Ashbridges Bay, Villiers Street; (4) Bank of 2-50's, Richmond and Bay Streets; (5) Transformer Bank, Gerrard and Belhaven, double ground; (6) Transformers on 4100, Danforth and Eaton; (7) Detail of car for current and voltage readings; (8) Outfit for changing oil in transformers; (9) Evenly distributed primary, Dundas Street, east of McCaul; (10) Taking Current and Voltage readings; (11) Detail of outfit for changing oil in transformers.

cularly the supplying of lighting and heating appliance loads, as these loads require closer voltage regulation than motor loads.

In the matter of supplying lighting and household appliance loads, statistics show that a greater demand exists for 115 volt equipment, especially lamps, than for other ratings. Now if the supply at the socket is to be at 115 volts our secondary lines must operate at a somewhat higher voltage depending upon the amount of voltage drop which we shall allow. For this purpose let us allow 2% drop in secondary lines and 2% drop in consumer's wiring. We shall then find it necessary to maintain a voltage of approximately 120 volts during periods of greatest load on our secondaries.

For our secondary system we have the choice of 120 volt 2 wire single phase, 120/240 volt 3 wire single phase, and various combinations of polyphase connection.

The polyphase combinations are not generally used and will be omitted from this discussion.

For equal conditions as to load, voltage drop, and losses, the relative copper requirements by simple calculation, assuming 2 wire single phase line as 100% are as follows:

120 volt single phase, 2 wire—100%.

120/240 volts, single phase, 3 wire—37.5% (neutral equal to each outer).

120/240 volt, single phase, 3 wire—31.25% (neutral equal to one-half each outer.)

This shows decided economy in use of 3 wire system, having neutral wire one-half the size of each outer.

The problem of secondary lines usually resolves itself into one of two classes:—

(1).—Lines with supply at one end and the load concentrated at the other.

(2).—Lines with supply at one end and the load distributed from one end to the other.

The first problem lends itself to easy calculation as the factors entering same are well known. This problem in city distribution is not often encountered. However, in city distribution or in thickly settled communities the load is generally of the distributed type. These secondary lines are often tied together at each end and supplied from a common bus forming a network.

For the solution of this problem, in which we shall assume the load as evenly distributed, we must know the total load distributed over the line, and also the distance of furthest consumer from the bus or transformer. Having chosen the allowable drop between bus and furthest consumer, say at 2%, we then have an allowable drop 2.4 volts, total load say to 20 amps at 240 volts and distance say 750 feet. It is well known that for evenly distributed load

$$E = IR/2 \text{ or } R = 2E/I$$

where $E = \text{Allowable drop}$

$I = \text{Total load current}$

$R = \text{Total circuit resistance.}$

$$R = 2 \times 2.4/20 = .24 \text{ ohms.}$$

i. e. 1500 feet of wire = .24 ohms.

1000 feet of wire = .16 ohms, which corresponds to No. 2 wire.

Using this method convenient tables can be calculated.

In the matter of voltage regulation it is clear that due to line drop the lamps near the bus are operating at 2% higher voltage than those at the other end. If voltage regulators maintain constant voltage on lamps at the bus then lamps at other end operate on voltage varying 2% between full load and no load. This is also true for lamps at the bus end if constant voltage is maintained at the lamps at distant end. In the former case the distant lamps at the loaded period operate at a voltage 2% below normal and in the latter the lamps near bus operate at a voltage 2% below normal the lamps near bus operate at a voltage 2%

Straightaway feeder curves—Evenly Distributed Load

above normal. However, if the regulators are adjusted to maintain constant voltage at lamps at a point between the bus and the distant end, so that on peak the rise in voltage of lamps at the bus equals the drop in voltage of lamps at distant end, then we shall find that with 2% difference in voltage between lamps at each end that the lamps at either end operate on voltage varying but 1% from normal, but in opposite directions. The point at which we should regulate to obtain this result is approximately one-third the distance from bus to other end.

Now if we are to allow a voltage change on the lamps on account of secondary drop of 2% it is evident that by using regulators adjusted for the one-third point we can use secondary conductors having twice the resistance found necessary for lines having constant voltage conditions at either end. Thus in the problem above we may use wire of .32 ohms per thousand feet. The nearest size corresponding to this is No. 5 wire, which has approximately one-half the weight of the No. 2 wire.

This gives an indication of the economy in secondary conductors made possible by the use of regulating equipment on our supply lines.

Transformers

It is apparent that with a secondary system, such as just described it will be necessary at period of maximum load to maintain approximately 120 volts at the transformer. Therefore, if transformers are to have the standard ratio of 20 to 1 they should have a normal primary rating of 2400 volts.

Transformers should be provided with several percentage taps on the primary winding. The reason for this will be discussed under primary lines.

Transformers should be operated to carry at least full load during period of maximum load. This is necessary from a standpoint of efficiency and economy, for which no idle transformer capacity should be installed on the lines. For this unused capacity we are getting no revenue return

with which to pay for the extra losses and capital investment charges such as interest, depreciation, etc. In addition to this there is capital tied up which might be put to more efficient use.

For the purpose of keeping the transformers loaded efficiently it is desirable that records and tests of maximum loadings be kept. This would enable us to see that no idle transformer capacity is installed, and also to avoid loading transformers to the danger point. In the case of transformers supplying power loads this is a comparatively simple matter as the number of consumers supplied from any one bank is small and connected load records are easily obtained. On account of heavy starting currents required on motors it is usually not advisable to carry in connected load more than about 150% of the rating of each power bank. This applies particularly to power banks rated under 75 kv.a. This is a rough rule. It is safer to check each bank by taking current readings at the maximum loaded periods, thus obtaining direct information.

However, in the case of supply for lighting and heating appliances where transformers are operated in banks supplying a common bus and distributing network it becomes practically impossible to keep a useful up-to-date record of connected loads on account of the constantly changing large number of consumers, and of the varying load conditions of individual consumers. In this case a good check can be obtained by taking current readings on the transformers during the hours of maximum load. The writer finds that these readings should be taken about once per month during the winter months. The load in summer months is comparatively light, and, therefore, readings are not required. These readings are conveniently taken by using a so-called "line testing set" consisting of split core current transformer and ammeter. This gives us directly the actual load demands on each transformer. The maximum load which any transformer may carry depends upon the temperature at which the transformer operates. Transforms

Straightaway feeder curves—2 1/2 per cent. taps on distant transformers

ers are usually designed by the makers to operate at full load continuously without exceeding 50 degrees C. rise in temperature when the surrounding temperature is 40 degrees C. This gives us the maximum temperature as 90 degrees C.

Transformers on house lighting service operate at their maximum loads during the winter months when temperatures are low, usually below 0 degrees C. and also during the evening when the temperature is usually somewhat lower than in the daytime. In addition to this they carry their maximum load not more than four or five hours, and for the balance of the day the load is very light. From this it can be seen that in order to reach the high temperature for which they are designed transformers must operate at consider-

ably more than full load during the hours of maximum load in the winter months. Under conditions of service such as this they can safely carry 50 per cent. overload without damage. Also during the long period when they carry little load they obtain an opportunity to cool down again to a comparatively low temperature.

In addition to information as to loading of the transformers these readings tell us how closely the loading is balanced on either side of the neutral. If the load is found to be unbalanced steps can easily be taken to reconnect service to bring about a balance. Connected load or consumers' demand records do not give us information on this point.

Straight-away feeder curves—Regulated at one-third distance

Where such records are relied upon there is a possibility of producing a heavy overload on one-half the transformer when connected for three wire operation and still not have a heavy total load on the transformer. There is, therefore, danger of burning out the transformer. Also if trouble develops on one side of the secondary system in the form of a short circuit well out from the transformer sufficient primary current may not flow to blow the primary fuse again producing a danger of a burn out.

When transformers supply three wire secondaries it is desirable to operate them connected for 10 volts, two in series across the outers. When so connected should the transformers on one side of the neutral blow their fuses due to any cause, only one-half of the transformer bank becomes inoperative as the other transformers will continue to supply service. Thus where two wire services are supplied but one-half the consumers are without light. When three wire services are supplied and these are becoming general particularly for store lighting, it follows that but one-half of each consumers' lights are out of commission, which is much less inconvenient than to have all lights out. The secondaries of transformers operating at 120 volts 3 wire must be grounded at the neutral point if three wire, and two wire one side must be grounded. For the purpose of grounding driven pipes at the side of the poles have formerly been largely used but these are found to be often of little use and are not recommended. Solid grounds should be installed. These are best obtained by connection to water mains or pipes, and if these are not available copper plates buried in coke should be used. These should be placed deep enough to lie in earth permanently moist.

All transformers should be protected by lightning arresters, placed on the same pole as the transformers. However, it is well to run a separate ground wire to the ground plate independent of the neutral grounding wire.

Primary Line

(c) Under primary lines will be included all lines intended to supply transformers having primary windings nom-

inally rated at 2,400 volts. As to choice of such lines we have the following:

- (1).—Single phase, 2 wire, 2400 volt.
- (2).—Three phase, 3 wire, 2400 volt (delta connected)
- (3).—Three phase, 3 wire, 2400 volt (star connected).
- (4).—Three phase, four wire, 2400 volt (star connected.)

There is also the two phase 2400 volt system having either 3, 4 or 5 wires, but on account of this being now more or less obsolete it shall be omitted from this discussion.

Now let us take up the question from standpoint of copper requirements. Easy calculations show that for equal conditions as to load, voltage regulations and losses, and assuming the copper required for the single phase 2 wire lines as 100 per cent., the following obtains:

Table 1—System	Copper Required
2 wire single phase 2400 V.	100%
3 wire three phase, 2,400 V. (delta)	75%
3 wire three phase, 2400 V. (star)	25%
4 wire three phase, 2400 V. (star)	29.16%
	(neutral wire one-half outer)
4 wire three phase, 2400 V. (star)	33.33%
	(neutral wire same as outer)

This clearly shows advantages in the choice of one of the 2400 volt Star connected systems.

Again let us decide as to nature of secondary service to be supplied. It is desirable to supply mixed lighting and power loads from the same primary lines to avoid duplication of feeder equipment and lines, more so if the power loads are moderate and do not overlap the lighting loads to any great extent. This condition allows the feeder regulating equipment to care exclusively for lighting loads when operating at maximum load, without interference from power load surges so detrimental to good regulation. Where considerable power load only has to be taken care of unregulated three phase feeders should be run as motor loads do not require closely regulated service. A choice of feeder

supplying exclusive power or mixed loads will, therefore, eliminate the choice of the single phase feeder leaving us the three phase systems.

Where three phase power loads are to be supplied it is often desirable to connect two transformers in open delta on secondary side, thus making it possible at any time to close the delta with a third transformer should a larger power demand occur. The reverse, of course, is desirable also and it should be possible to continue service if one transformer (where three are used) becomes defective. This condition can be handled by the three wire three phase

delta system and by the four wire three phase star system. This cannot, however, be supplied from the three wire star connected system.

Referring to the matter of regulating equipment required for lighting loads the three phase 4 wire system has decided advantages. With a single phase regulator on each phase wire this can be adjusted to act independently without interference through load condition on the other phases. The regulator action is quite stable and compares in this respect to the single phase feeder and regulator. This is not the case in regulating delta connected feeders where unbalancing of loads on the various phases cannot be so nicely taken care of. Changes of this kind usually effect all phases. Another feature which is in favor of the 4 wire star connected system is the fact that on account of the higher voltage between phase wires it is possible to transmit with equal sized conductors and with equal voltage drop any given load approximately three times the distance possible in the delta system. This is desirable where loads in suburban districts have to be handled.

The above considerations would lead us to the adoption of 4 wire star connected system.

Where a heavy secondary network is to be supplied the neutral wire of this can be used as a common neutral for the primary lines as well, thus saving an additional wire and giving us the economy in copper of the 2400 volt 3 wire star connected system.

As in the case of secondary lines the problem resolves itself into the two general classes:

- (1).—Lines with load concentrated at the end.
- (2).—Lines with load distributed from one end to the other.

The distributed form of load is more commonly encountered

L^2/R and weight of Feeder in "Feeder Main" = $\frac{1}{2}$ this or $\frac{1}{2} L^2/2R \times \text{constant}$.

The mains are of length "L" and of same weight as the feeder or = $\text{Constant} \times L^2/2R$.

Therefore the mains of length "L" have resistance "2R" or each main of length $L/2$ has resistance "R".

Now drop in straightaway feeder = $IR/2$ (shown above).

Then for feeder and main system we have:—

Drop in feeder portion $IR/2$, i.e. drop in feeder of resistance $R/2$ with load I concentrated at one end.

And drop in main $1/2 \times R/2$ since this is distributed load of current = $1/2 I$ and resistance R.

Therefore Total drop = $IR/2 + IR/4 = 3IR/4$.

Thus we see that for straight-away feeder we have less drop to most distant transformer than in the feeder and main system for equal costs as to copper used. Therefore, this system should be used where constant voltage is being maintained at the station and feeder voltage regulating devices are not used.

Now let us consider the use of feeder voltage regulators.

In the "Straightaway" feeder there is a total drop of $IR/2$ and if we regulate for the $1/3$ point as discussed under secondary lines we have a variation of voltage due to line drop of $IR/4$ delivered to transformers at either end of the feeder.

Now in the case of feeder and main system above discussed, if we regulate for the $1/3$ point between centre of distribution and the end of the mains we have a variation of only $IR/8$ since total drop in the main is $IR/4$.

Thus we have only one-half the variation between transformer although we have more total line drop.

If we assume $IR/2 = 4\%$ or 96 volts on 2400 volt line we can tabulate for easy reference the following:

Full Load Conditions.

Total Primary line drop Station to most distant transformer.
Line drop to nearest transformer.
Difference in voltage between nearest and furthest transformer.
If regulating equipment takes care of one-half this drop maximum difference of voltage applied to transformers

Single Feeder ($IR/2$)	Feeder & Mains $96 \text{ Volts } IR/2 + IR/4$
96 Volts	144 Volts
0 Volts	96 Volts
$IR/2$	$IR/4$
96 Volts	48 Volts
$IR/4$	$IR/8$
48 Volts	24 Volts

tered; and for the purpose of this discussion we will assume that the load is evenly distributed.

For the supply of such loads we have two general schemes of primary layout, namely the straightaway feeder with small branches and the centre of distribution or "feeder and main" system.

In the straightaway feeder loads are taken off along the line while in the feeder and main types the feeder is run to a centre of distribution at the centre of the load and mains are run in all directions from this centre. No loads are taken off the feeder between the station and the centre of distribution but are all taken off the mains.

Let us assume a case of feeder of length "L" with load evenly distributed along its whole length. The total load in amperes = I. Consider but one wire of length "L" having resistance R.

Then for evenly distributed load the drop $E = IR/2$ or $R = 2E/I$.

Now compare this with a feeder and main where the feeder is run to a point $L/2$ from the station and two mains are run one back to the station and one to distant end L. Suppose we wish to use same amount of copper as in straightaway line we then have feeder of resistance = $R/2$ and two mains together of length "L" whose weight is the same as feeder whose length is $L/2$ and resistance $R/2$.

Now weight of conductor = constant $\times$ length²/Resistance.

Then weight of straightaway conductor = Constant $\times$

It is clear that when feeder regulators are used compensating for line drop that closer regulation can be obtained on feeder and main system.

Now take the case of a feeder which is supplied with constant voltage at the station end and no compensating apparatus for line drop is used. Suppose also that we allow 10 per cent. primary line drop it is clear that on peak the most distant transformer operates on but 90 per cent. of normal voltage and neglecting transformer regulation and secondary drop, lamps on this transformer are receiving only 90 per cent. of rated voltage. If now we operate this transformer on a 5 per cent. tap in the primary winding we shall deliver 95 per cent. of rated voltage to the lamps, and deliver 105 per cent. of rated voltage at no load. Thus on peak when 100 per cent. of lamp load is in service these are receiving 95 per cent. of rated voltage instead of 90 per cent. and no load, when few lamps are affected, we deliver 105 per cent. volts instead of 100 per cent. Thus by the use of the tap we deliver better average service at the lamp than without.

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

Inspection Trip Over Chippawa Power Development

The convention wound up on Saturday morning with a trip over the Chippawa Power Development work of the Ontario Commission. A brief description of the work to date is given herewith, with typical illustrations to indicate the various operations and the stage of their advancement.

Thirteen-Mile Canal

The route of the big canal which will carry the water to the turbines at Queenston is shown in the map herewith. This route is about $12\frac{3}{4}$ miles long, with the intake on the Niagara River at Hog Island, Chippawa, about two miles above Niagara Falls. The tailrace is on the Niagara River about one mile above Queenston. The intake will be in what is known as the Grass Island Pool of the Niagara River. The mean monthly elevation of this pool varies about one foot.

The normal elevation of Lake Erie is 573 feet; of Grass Island Pool, 563; of the proposed power house site, 247; and of Lake Ontario, 245. Probably no river has a more uniform regimen than the Niagara. The minimum flow is about half the maximum, and over a period of fifty years the maximum difference in mean monthly levels under normal conditions, either at Queenston or Chippawa, amounts to only about six feet.

The best intake and power house locations were first determined upon, with a view to the maximum utilization of the available head, and contours and borings were then studied to decide by what route a canal could connect those two points to the best hydraulic and economic advantage. The intake was located at Hog Island partly on account of that point being just above the critical section at which the water begins to speed up for its passage over the Falls. Location further up the river would have meant a larger canal and further downstream would have necessitated a loss of head. Another reason equally important for locating the intake at Chippawa was the use which could be made of the natural channel of the Welland River—often called Chippawa Creek—which comprises about $4\frac{1}{4}$ miles of the route of the Canal, leaving only about $8\frac{1}{2}$ miles to be excavated, although the Welland River will have to be somewhat deepened. The flow of the Welland River, which is a sluggish stream with a very flat gradient, will be reversed for this $4\frac{1}{4}$ miles.

$8\frac{1}{2}$ Miles Excavation

This $8\frac{1}{2}$ miles of excavated section compares with $19\frac{1}{2}$ miles for the old Jordan-Erie scheme, and the net head is 305 feet, compared with a possible 299 feet for the Jordan-Erie project. (See map).

The gradients adopted for the canal average about one foot per mile, or a total of about eight feet in the $8\frac{1}{2}$ miles of excavated canal. The loss of head in the penstocks, due to friction, may amount to upwards of two and a half feet, and the loss in the Welland River from Hog Island to Montrose, where the excavated canal begins, will be about 6 inches, under maximum load, so that the total loss of head will be about 11 feet, making the net effective head about three hundred and five feet under normal conditions.

Thus, of the 327 feet normal difference in level between the two lakes, only 22 feet head will be lost—10 feet between Lake Erie and Hog Island, 11 feet between the intake and the tailrace, and two feet between the point of discharge of the tail water and Lake Ontario.

The power house will be located in the bottom of the gorge, about three-quarters of a mile above the Lewiston

Bridge, just below where the last rough water disappears. The cliffs the nearly vertical at this point, and as the gate-house will be on the cliff immediately above the power house, the penstocks will be nearly vertical and only about 450 feet long, thus reducing cost and head loss to a minimum.

With this scheme of development about 30 h.p. will be obtained from each second-foot of water used, compared with about 14 h.p. per second-foot obtained by the existing plants at Niagara Falls. With 36,000, the whole treaty allotment of second feet available, over 1,000,000 h.p. can be developed.

All of the excavated section of the canal will be in solid rock, with the exception of $1\frac{1}{4}$ miles of earth section running north from the Welland River and half a mile of earth section across the whirlpool ravine. These sections will be trapezoidal in shape, lined with rip-rap. The section at the whirlpool will also be faced with concrete.

Rock Section

The rock section is 48 feet wide at the bottom, with perpendicular sides, the average wetted section being 35 feet deep and lined with concrete. The velocity in the rock section will be about 6 feet per second when the plant is under maximum load. The earth overburden above the rock surface will be generally sloped $1\frac{1}{2}$ to 1, but a flatter slope is provided for where local conditions require it.

The Commission has purchased a tract of land as a right-of-way which will be sufficient for all present and future needs. This right-of-way includes about 200 acres near St. David's which will be used as a dump for the disposal of excavated earth and rock.

At a point 2,400 feet distant from the gatehouse, the canal begins to widen into the forebay, the forebay gradually increasing in width to four hundred feet, which will be the approximate overall length of the gate house. The initial development provides for four steel penstocks each about 14 feet in diameter, 450 feet long; and one exciter penstock, about 5 feet diameter.

Provision is being made for the installation of four main generating units each of 50,000 h.p. capacity. Both the gate house and the power house are so designed that they may be extended whenever conditions warrant.

The surveys for the work were begun in 1914 and continued for nearly two years. During the year 1917 the construction plant was brought onto the job and assembled, and during the first part of 1918 the camps were completed.

The Three Largest Shovels Ever Built

The main equipment for the earth and rock excavation consists of three of the largest electrically driven shovels ever built. They are of the revolving type, built by the Bucyrus Company, and are fitted with an 8-cubic-yard bucket for excavation in earth, and a 5-cubic-yard for rock work. The boom on these shovels is about 90 feet long, and the dipper stick, 58 feet. Either shovel can load dump-cars which stand on a track the level of which is 62 feet above the level of the track on which the shovel stands. The shovel rests on two tracks (four rails) 30 feet centre to centre and is mounted on 16 wheels. The nominal horsepower of each of the two shovels is 715 h.p., upon a half-hour intermittent rating. Each shovel weighs over 300 tons, contains 75 tons of ballast, and has a capacity of 3,000 to 5,000 cubic yards per 10 hour day when handling earth.

There are also five other electrically-driven shovels at

(2) View of forebay immediately following shot. (3) Looking up canal excavation from forebay. (4) Crusher plant. The rock is coarse crushed in the building at the left, transported on belt conveyor to the second building containing secondary crushers, and finally hoisted to the screen house on the extreme right of the picture. (5) Showing Lidgerwood cable bucket in operation, just rising with its 3-ton load; this bucket makes a trip every 2 minutes. (6) Large disposal area, showing load being dumped, also movable trolley-pole line. (7) Another view of disposal area; train of cars in distance being unloaded. (8) Dredging work under way at Hog Island, at entrance to Welland river; scows in distance being unloaded.

One of the electric locomotives. Note the double trolley arrangement, two poles on each side

work, having dipper capacities ranging from $\frac{7}{8}$ cubic yards to $4\frac{1}{2}$ cubic yards.

On the Welland River section of the canal, a Lidgerwood cable excavator is at work, fitted with a 3-cubic-yard Anderson-Evans clam. The cableway has an 80-foot head tower and 60-foot tail tower, and a span of 800 feet. The excavated material is being disposed of along the north bank of the river. The width of the Welland River at the water line averages about 300 feet.

The Commission has purchased one hundred and fifty 20-yard Western airdump cars, each of 80,000 pounds capacity; also seven 40-ton steam locomotives and twelve 50-ton electric locomotives. The steam locomotives are switchers purchased from the Pennsylvania Railroad. The electric locomotives were built by the National Steel Car Company, Limited, of Hamilton, Ontario, six of them being constructed with General Electric equipment and six with Westinghouse equipment. Two pile-drivers are at work on the river section. There are three 40-ton and two 15-ton Bay City locomotive cranes for general utility work.

15,000,000 Cubic Yards of Excavation

It is estimated that 9,000,000 cubic yards of earth and 4,000,000 cubic yards of rock must be removed from the excavated section; and from the river section, 2,000,000 cubic yards of material, mostly earth.

At the present time the material which is being excavated from the Whirlpool sections is being used to fill the old Whirlpool gully, but the main dump, as already noted, will be at St. David's. A double-track railway line runs the full length of the canal from Montrose to the forebay, and a $2\frac{1}{2}$ mile span connects the main line with the St. David's dump.

There will be various other branches of the railway constructed from time to time as needed. A railway will probably be built from the power house to connect with the Michigan Central at Queenston to bring in the machinery

and to take out the materials excavated from the power house substructure.

The railroad lines are all electrified, the trolley wires being offset to one side of the track, and carried in clamps devised by the Commission's line construction department. These clamps and the hangers which suspend them from the poles are all made up of standard material, and are so arranged that the temporary use of the material does not injure it.

Framed timber trestles are set alongside the dump and other temporary tracks to carry the trolley wire. These trestles are mounted on wheels or skids and can be removed readily by a locomotive crane when it is necessary to shift the track.

In the Whirlpool yards is located a large repair shop containing drills, shapers, planers, lathes, forges, steam-hammers and wood-working machines. The Commission has built about eighty buildings, including bunk houses, freight houses, offices, machine shop, storehouses, substation, etc.; also a number of buildings are used which were on various parcels of purchased property.

Gunite Buildings

Most of the buildings are of frame construction, but are being "gunited" on the outside over tar paper and wire mesh, using 1 to 3 mix of cement and sand. Sharp concrete sand is being used and the "gunite" applied with cement-guns. The substation, machine shop and all of the more important buildings have already been fireproofed in this manner, and it is the intention to "gunite" most of the

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

other buildings. The bunkhouses are comfortably arranged on the cottage plan.

The crushing plant is located on the forebay. It is equipped with three secondary crushers of the gyratory type and one 4 in. x 60 in. Taylor jaw crusher which will have a minimum capacity of 2,000 cubic yards of crushed stone per day.

The rock excavation at the forebay is loaded into skips which are picked up by a locomotive crane and which

Centering for one of the concrete bridges over the Chippawa power canal

dump into a bin. A belt conveyor carries the stone from the bin to the crushers and from thence by another conveyor to the cars.

There are four railway bridges to be constructed over the canal, one for the Niagara, St. Catharines and Toronto Railway (electric), one for the Wabash Railroad, one for the Grand Trunk and Michigan Central Railroads. These will be reinforced concrete arch bridges. There will also have to be constructed a number of highways and foot bridges to carry the various roads across the canal.

Several hydraulic models are being prepared at Dufferin Islands, near the Ontario Power Company's intake in the Niagara River. These models are based on designs prepared by the Commission and are for the purpose of studying the design of the intake at Hog Island. The design of the intake works will be based upon the results of these studies.

Trade Publication

Metal Molding—The National Metal Molding Company, Pittsburgh, Pa., have distributed a reference chart for wiremen showing the various fittings and devices used in connection with No. 222 two-wire and No. 333 three and four-wire "National" metal molding which, it is pointed out, are inter-connecting. This chart is suitable for hanging up in the shop and a complete pocket-size descriptive bulletin will be sent by the company on request.

The shareholders of the North American Pulp & Paper Companies have approved of the organization of a company—the Saguenay Pulp & Power Co.—to take over the Saguenay Power & Light Co. and the power plants and other properties of pulp and paper companies. The new company will obtain possession of water powers capable of produc-

ing 200,000 h.p., of which its subsidiaries are now using 30,000 h.p., this including current for light and power for several villages.

Schedule of Motor Sizes for Farms

The Westinghouse Electric and Manufacturing Company have prepared the following list of motors as suitable for the various appliances now rapidly becoming standard for farm workers. Conditions will vary, of course, but the list will at least provide a basis from which to make an intelligent estimate.

Machine	Motor Horsepower		Size Most Used
	Minimum	Maximum	
Feed grinders (small)	3	10	3
Feed grinders (large)	10	30	15
Ensilage cutters	10	25	15 to 20
Shredders and huskers	10	20	15
Threshers, 19-in. cylinder	12	18	15
Threshers, 32-in. cylinder	30	50	40
Corn shellers, single hole	3/4	1 1/2	1
Power shellers	10	15	15
Fanning mills	...	...	1/4
Grain grinders	...	...	1/4
Grain elevators	1/2	5	3
Concrete mixers	2	10	5
Groomers (vacuum system)	1	3	2
Groomers (revolving)	1	2	1
Hay hoists	3	15	5
Root cutters	1	5	2
Cord wood saws	3	10	5
Wood splitters	1	4	2
Hay balers	3	25	7 1/2
Oat crushers	2	10	5
Cidermills	2	5	2 1/2
Clover cutters	1/4	1/2	1/2
Water pumps	1/2	5	3
Cream separators	1/10	1/4	1/8
Butter churns	1/8	3	1/4
Milking machines	3	5	5
Bottle washers	1/8	3/4	1/2
Vacuum system	2	3	3
Refrigeration	1/2	25	3 to 5
Grindstones	1/8	1/4	1/4
Emery wheels	1/4	1	1/4
Lathes	1/4	1/2	1/2
Forge blowers	1/15	1/8	1/10
Sewing machines	1/40	1/30	1/30
Buffers and grinders	1/40	1/30	1/30
Portable vacuum cleaners	1/83	1/45	1/83
Large ice cream freezers	1/8	1/4	1/8
Washing machines	1/8	2	to 1/4
Centrifugal dryers	1	2	1
Mangles	1/4	1	1/2
Meat grinders	1/4	3/4	1/4
Sausage stuffers	1/2	1	1/2
Water pumps	1/4	1	1/2

Real Service

A citizen went into an electric shop in Toronto, recently, to purchase some base plugs. He was told they were an old style; the store didn't stock them. Did he know where they could be got? No, the only thing for the customer to do was try some of the other electric stores. One of the "other stores," fortunately, had a different way of handling these matters. The customer was told: "No, we don't stock them as they are rather out of date, but just leave your order and we'll have them for you inside of a day."

That's a considerable difference in store service. Is there any doubt about which store the customer will go to for future purchases?

The annual convention of the Illuminating Engineering Society will be held in the Hotel Sherman, Chicago, October 20-23. At the annual election of officers of the society, held on June 12, Mr. S. E. Doane was elected president.

The Contractor-Dealer

The Contractor-Dealer of Tomorrow—Some Suggestions as to the Immediate Fields to be Covered are Offered for Practical Consideration by Mr. John C. Rendler, President Southern California Electric Company*

"There is a tide in the affairs of men, which taken at the flood, leads on to fortune;
Omitted, all the voyage of their life is bound in shallows and in miseries."
On such a full sea are we now afloat, and we must take the current when it serves, or lose our ventures."

How well the words of Shakespeare will apply to the Electrical Contractor-Dealer of Tomorrow, time alone can tell. Are we ready to take the current when it serves? I say we are. In order to more clearly define the scope of the "contractor" from that of the "dealer" and because there is a distinction between the two, I am going to deal with them separately.

The Future Contractor

The Contractor of Tomorrow is a man neat and clean in his personal appearance, his associates are architects, building contractors, and proprietors of commercial and industrial businesses. He will have a thorough knowledge of his business, its possibilities for development, expansion and opportunities. He will use only highgrade materials and employ good machines, because no business can progress on any other principle.

The contractor will consider his vocation worthy and as affording him an opportunity to serve society. Society demands honorable business methods and unless a business is constructed on such a foundation, all of our ventures will be lost. We will associate with men who compose the other branches of the industry, make our dealings with them, as also our competitors, on an ethical basis, thereby retaining their friendship, have access to their council and advice, keep abreast with the times, particularly in our own industry, then, and not until then, take the current when it serves.

Residential Work

In residences and apartment houses, too little attention has been paid to correct illumination, wiring for lamp socket and heavy wattage appliances. We so often find a residence in which the wiring has been poorly laid out. The general illumination is not sufficient for the room, the color of the walls and ceiling have received no consideration, the fixtures are selected from the standpoint of beauty and price rather than efficiency, and a harmonizing effect. The switch locations are placed at the most convenient place for the contractor, rather, than for the consumer. I have seen some very nice residences and apartments, recently constructed, with no provision for the many labor-saving, lamp socket devices. Here the Contractor of Tomorrow will demonstrate his knowledge. No residence or apartment house will be wired by him, or under his supervision, that does not have provision in every room for a plug, of sufficient capacity for

660 watts. In addition to these, provision will be made for the special plugs to care for the washer, cleaner, iron, toaster, percolator, and the curling iron in Madame's boudoir. A few other important provisions should be made. No modern residence or apartment owner, will be permitted to overlook the necessity of providing for the electric range, water heater, or large air heater. While these electric devices are prohibitive in some localities at the present time, there is no doubt in my mind that they will be as universally used as the electric iron, and in a very short time. Special care will be given to the wiring of all lamp sockets and heavy wattage appliances, to see that the circuits are wired heavy enough to carry the full load, proper fusing facilities, and entirely separate from lighting system. The time to have these provisions made in the wiring is, before the plans leave the architect's office, therefore the contractor will lend every effort to see that the architect is fully conversant with the advisability, and necessity, of providing base plugs and special outlets. While I have used the residence and apartment house in my discussion, the same condition holds true to quite an extent in office buildings and to, have even greater extent in some.

The Industrial Field

Here the contractor will grasp the opportunity, which for numerous reasons in the past, he neglected to take. By hard and consistent effort, both as to salesmanship and, a better understanding of their requirements, he will win back the thousands of dollars in business that he has lost, on account of the industrials doing their own work.

Make a study of power and the relative values of it, so you can show the economy of individual drive on machinery over the long line shaft and belts that are largely in use today. Show the many advantages of electric drive over gasoline, or steam, to those who are still inclined to believe they have

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

the best system of power. Show the manufacturer how he can increase his production, by better lighting in the factory general, and by properly lighting the individual machine. The safety of employees in the factory is very essential, therefore recommend and use necessary safety devices that will add to the protection of life and property. All motor maintenance will be done by the contractor, when he puts himself in a position to render service. A motor stopped in a manufacturing plant means the loss of time of one or more men, but this is small compared to loss entailed by the cutting off of the output of that machine. We must be ready to give instant service, make the repairs as quickly as possible, commensurate with good workmanship, charge a fair price for the labor performed and the material furnished, thus giving such efficient service that the ordinary industrial

* Before the N.E.L.A.

plant cannot afford to maintain its own electrical department.

Again, we have an opportunity to demonstrate the many advantages of heavy wattage appliances, this time in the factory. Electric furnaces, ovens, spot welders, glue pots and hot plates are all tried and proven devices, and an opportunity should never be overlooked to recommend their use.

There are one or two obstacles which stand between the contractor and the industrial business, which I firmly believe when the contractor shows he is making every effort to secure this business, that he is deserving of it, that the jobber will see the fallacy of recognizing every industrial as a trade buyer. The manufacturer of motors will discontinue selling their product direct to the consumer, and will revise their policy, allowing the contractor a sufficient margin of profit to warrant his doing the sales and engineering work. The contractor, who is not an electrical engineer, may not be aware of the fact that most power companies maintain a corps of engineers who will lend him, without charge, any

assistance desired, in laying out new plants or remodelling old ones. The offer of this service should be appreciated and used advisedly.

Electricity on the Farm

A large, new and undeveloped field is open to the electrical contractor in the use of electricity on the farm. I have a vision of driving out the country boulevard and stopping at the modern farm. The first thing we notice is the light at the entrance gate; as we drive in we find the yard and all the buildings are lighted on the outside. On entering the milking room we find that electric milkers are used exclusively, the building is well lighted, and motor-driven conveyors are used for handling the milk and feed. In another small building we find the food chopper electrically driven. The separator, the churn and ice-cream freezer are driven by motor, and in the laundry the washing machine and iron hold forth ready to perform their service at the touch of the button. In the barn, we find a motor connected to a hoist, for the purpose of raising the feed to the loft, or loading the

Officers of the newly formed Montreal Electrical Contractors' Association

Mr. R. Moncel, President

Mr. F. J. Parsons, Vice-President

Mr. H. Vincent, Executive Committee

Mr. J. A. St. Amour, Executive Committee

Members of the Montreal Electrical Contractors' Association decided, at a recent meeting, not to recognize the union; the demands of the union being regarded as preposterous. The wiremen have gone on strike, but, at a further meeting on June 24, it was decided by association members to sit tight and await developments. Some of the contractors state they are not affected—most of the men being at work.

wagon. All the wood is sawed by an electrically driven saw. The water the farmer drinks and that with which he irrigates his land, are pumped by an electrically driven motor. In fact, I believe the modern farmer has become so energized with the electrical idea that he is largely propelled by the thought of it.

What has been said about wiring, switches, base plugs and heavy wattage appliances for the residence and apartment house, apply equally as well in the modern farm house. In fact, the heavy wattage appliances are more essential on the farm, because in most cases gas is not available for heat or cooking.

In localities where there is no power available, another field opens to the contractor—that of furnishing farm lighting plants complete. I would not recommend one in a place where a public service corporation could serve, because the private plant is limited in its capacity, requires more care, and the first cost is quite a factor. Also, the private plant cannot be operated as economically as the power company's service can be purchased. The possibilities, however, for wiring and motors in the private plant are similar, with the exception of their limited capacity. With the modern farm, having from one to ten motors a good business in maintenance may be worked up by the contractor, and what has already been said about service, in industrials, applies equally well here. By all means make the farm wiring and installation comply with all state safety rules, even though it may not be inspected. With this tremendous field open to the contractor now, almost at its birth, he will do well to fit himself for immediate action, grasp this opportunity, for some one surely will, and let it not be a plumber or a blacksmith.

I have endeavored to cover some of the problems of the Electrical Contractor of Tomorrow, and to suggest solutions of these problems; it is now my purpose to enumerate some of the opportunities of which the Electrical Dealer of Tomorrow will take advantage.

The Dealer

Considerable has been said about the electrical dealer as a merchant, all of which has been very instructive to him. I believe, however, that as he is young in a business way, he must, as a child, learn to crawl before he can walk. In establishing a location, two things must be borne in mind: First, the traffic or shopping procession; second, the possibilities of the city's future development. These two things for permanency, as establishment in a particular location is a valuable asset to a merchant. A move is very expensive. The selection of a store, whether it be on a corner, or in the middle of the block, depends upon the rent, and more particularly upon the gross profit upon which you work in the sale of your merchandise. The gross profit allowed the electrical merchant today does not permit of him opening a store in the heart of a shopping district.

A location being selected, "regardless of the district," too much consideration cannot be given to the furnishings. A carpeted floor, if possible, enclosed glass wall cases and show cases, to properly display merchandise and to keep it clean. The shelves where the small devices are kept, should receive especial attention, for there are a number of stores whose general good furnishings are marred by the appearance of their shelves. The store, wall and show cases should be well lighted, thereby offering the suggestion to your customers of better light. If the store arrangement will permit of it, I would have two windows, so that one would always be on display, while the other was being trimmed. To obtain the best results, a window should be trimmed once every week, concentrating your display on one thing, rather than trying to show everything you have in your establishment. A valuable lesson has been taught to the dealer, which the

Dealer of Tomorrow will take advantage of—that of stocking inferior merchandise and appliances. No appliance, device or merchandise will be put on the shelves for sale, that does not carry the personal guarantee of the dealer. The time has passed when a customer, bringing in a defective article, will be told that it will have to be sent to the manufacturer for replacement. I firmly believe that had this policy been in effect for the past five years, the electrical dealer would today be doing 50 per cent. more business. The consumers finding that the electrical merchant's wares were no better, and his service poorer, they made their purchases at the hardware, department, and grocery stores on account of their convenience.

Next to highclass merchandise for sale, comes the necessity of highclass salesmen to sell it. A salesman will either bring repeat customers or drive them away. See that your salesmen are possessed of good personality, understand your merchandise thoroughly, are well dressed and neat in appearance, though not expensively; are kind and courteous, and your business will grow by leaps and bounds. Install a good delivery and repair service; it is necessary, as the customer has been educated to expect and demand these things. Join your Association, your Chamber of Commerce, your Rotary Club, or any other business organization that is interested in building up your city; and thereby take your place in the front ranks of your city's business activities.

Business Building

A short time ago this part of the dealer's business was a puzzle of considerable moment to him. At each thought of some plan to build new business, he was confronted with the plan then in effect by the power company. He could not sell at their prices, meet term payment plans, or make repairs free of charge. Happily, this is a thing of the past. Again I ask, "Will the electric dealer take the current when it serves?" I answer, "He will." How is he to go about it?

He will advertise to the limit of his financial possibility, his name, his business and his location. Let me say here, that I do not believe it would be amiss if the manufacturer apportioned some of his national advertising fund for use in fertile local fields. Since practically all agencies for specialties and appliances are exclusive, and are distributed through an electrical jobber, he also should do local advertising in some form, either through the newspapers or by campaign, always referring to the dealer as his sales agent. The dealer will do seasonable campaigning, employing highclass salesmen to canvass the city, in the same manner as formerly employed by the power companies. The adoption of the term payment plan on the larger devices, is absolute necessary, and properly handled will be the best business builder the dealer has. Advertise this feature of your business at all times. Select a good standard line that is well advertised nationally, and then show in your advertising why this commodity should be purchased from you, rather than elsewhere. Tell the public about your service department, your personal guarantee, your knowledge of things electrical, all of which will enable you to serve them better. Your window is your best salesman. Make use of it. Tell your story to the passerby so that he gets it at a glance, and once you get him in your store, good salesmanship will do the rest. We must get our name and business before the public, and in much larger type than we have been able to do in the past. The down-to-the-minute dealer is soliciting consumer lamp contracts. The lamp business is not only profitable in itself, but serves as bringing additional business from the consumer. The dealer's progressiveness will lead him into many fields in which the harvest is very poor now, among them the office building and some industrials. By his consistent effort and progression, the jobbers and manufacturers who are now serving this class of trade, will see the advisability of discontinuing their

Goodwin says the "best" form of advertising is the well dressed window. Cowan's, of Brantford (T. A. Cowan and C. D. Henderson), used this fine June bride display. Mr. W. B. Hutton is manager of the electrical department.

efforts, and leave the work and the business to the dealer. No jobber or manufacturer should solicit or accept a consumer lamp contract, when there are progressive dealers in the vicinity.

A manufacturer should not sell motors direct to the consumer, when he finds the dealer ready to perform the service that is necessary. In other words, when the dealer perfects his selling force to its highest efficiency, his only competition will be from his competitor dealer, and then on an ethical basis.

Accounting and Collections

As we develop our business, its growth demands of us a better accounting and collection system. Adopting the term payment plan for selling merchandise, without developing an accounting and collection system to handle it, would recommend a separate ledger for all term accounts, using a card follow-up system. Adopt a policy at once, allowing not more than two payments to lapse without taking back the merchandise. Notify your customer about five days in advance of date payment will be due. Try to get them to come to your store to make their payments—it means additional business to you. Use good judgment when sickness or accident prevent a customer from paying, but accept no fake story. If you have sold good merchandise at an honest price, you are entitled to be paid for it. Numerous failures are recorded on account of poor collecting methods, and the fear of hurting your customer's feelings, by asking them for what is justly due you. The accounting department should be so kept that you can get complete information regarding any part of your business. Your monthly report should be as complete as your annual report, with the exception of a physical inventory. The merchandise account should show you the number of times per year you turn your stock. Your sales account is your stimulator, and you are the stimulator for your organization. It also gives you the figure from which to make your advertising appropriations. It shows you the advantage of discounting your bills. You get a monthly comparison of one month with the next. Also, comparing a month with same month of the year past, you can ascer-

tain if you are maintaining a steady growth. Each department should be kept separately, and bear its ratio of the general expense; in this way you know from where your profits are derived, as well as the source of losses. I know of a case where a department had been losing approximately \$350 per month for two years, and it was never found out until a good accounting system had been put in. I believe it is the best money a dealer can spend.

Another vital point of your business that is brought to your attention by a good accounting system, is your cost of doing business. You must constantly watch this important item, or your expense will grow without your noticing it. A good form for this is to have your bookkeeper list your overhead on a separate sheet in monthly order, so that at a glance you can see the comparisons.

The Consumer's Good Will

There is nothing so essential to the success of our business as the good will of the consumer. It is easy to discuss the progress of the contractor-dealer, the many new fields in which he has to work, and the planning of this work, but the success of it all is in the hands of the consumer. We can obtain this good will only by preparing ourselves to be generous in the extension of good will to others. Make as the main policy of our business. Honesty and Fair Dealing; inculcate this idea in the minds of our organization, advertise it, then by all means, practice it, and we will be doing justice to the consumer, to ourselves, and to our profession.

In summing up the possibilities of the Contractor-Dealer of Tomorrow, it seems to me, there never was a time in the history of the electrical business when opportunities such as we now enjoy were within our grasp. I should say it is now up to us to show that we are capable of handling the situation, of putting forth renewed effort, or re-energizing our selling forces, of establishing new forces to care for new fields, of living up to the claims we have made in our own behalf, and show in the words of Shakespeare, that, "On such a full sea are we now afloat" we will "Take the current when it serves" and so "Lead on to fortune."

New Book

Induction Coils—By Professor F. E. Austin, E.E., Hanover, N.H.; published by the author; price \$1.00. It is the aim of this book to so present an explanation of the fundamental principles as to enable anyone to construct induction coils to fulfill specific requirements. The author points out the importance of the induction coil without which the gasoline-driven automobile would be impossible; nor could there be telephony over any but short distances. The induction coil has also made wireless telegraphy possible and also the application of "X" rays in both diagnosis and therapeutics. Those who desire to construct coils to operate wireless outfits will find specific instructions in this book for building coils for large and small ranges. Much of the material presented is the result of the author's experience in directing the courses in Radio and Buzzer Training, Dartmouth Training Detachment of the U. S. National Army.

New Power Plant for Dominion Steel Co.

The Dominion Steel Corporation, it is announced by Mr. Mark Workman, the president, have decided to install a new electrical power plant, to supplement the present equipment. The plant will be operated by waste gases from the blast furnaces, and will not only provide a safe margin over existing requirements, but will furnish sufficient additional power to take care of the needs of mills and other plants now operated by steam. The plans include the eventual electrification of practically all the apparatus now operated by steam power, such as the blooming mill, rail mill, loading and discharging apparatus at the piers, etc., and will promote large economies.

C-H Seventy-Fifty Switches

The Benjamin Electric Manufacturing Company of Canada, point out to dealers the dissatisfaction that often results to users of electric appliances by habitual pulling out of the terminal connectors of electric irons, toasters, and so on. The flashing at the terminal that inevitably results

with a worn cord has doubtless been the cause of frightening many women from the further use of their appliances. The C-H Seventy Fifty switch has been designed to remedy this difficulty. Dealers not only find them ready and profitable sellers, but also that they increase the comfort and convenience customers derive from their appliances and, consequently, leave them in a favorable frame of mind for further sales.

American Beauty "Quad" Heater

The illustration herewith shows a new quadruple radiant heater, called the "American Beauty Quad," manufactured by the American Electrical Heater Company, Detroit, Mich. This is similar in design to the twin radiant heater; it has removable heating elements and guards and movable reflectors. Each element is rated at 330 watts, making the com-

bined demand 1320 watts. However, all four units need not be used at once as there is a push switch provided for the upper pair, and another for the lower pair. The unit may be used as a portable or may be permanently mounted on a wall. Attention is called to the fact that heat may be sent in one or several directions at the same time, because of the movable reflectors.

National Tube Co. Distributors

The National Tube Company, Pittsburgh, Pa., announce that they have made arrangements with the National Metal Molding Company, of Pittsburgh, and the American Circular Loom Company, of New York, to act as their distributors of Spellerized Mild Steel Tubing, made especially for the manufacture of rigid steel conduits. These two companies will, as heretofore, finish and market this tubing under the following trade names: the National Metal Molding Company—"Sherarduct," a sherardized rigid steel conduit, and "Economy," a black enameled rigid steel conduit; the American Circular Loom Company—"Xduct," a galvanized rigid steel conduit, and "Electroduct," a black enameled rigid steel conduit.

San-Fer-Ann Annunciator

Edwards and Company, of New York City, are putting on the market their San-Fer-Ann annunciator, illustrated herewith. The San-Fer-Ann is a high grade instrument, the case being made of steel, white enamelled finish, with nickel plated ball and trimmings. The drop openings are fitted with glass, and the case is securely fastened to the back board with hinges on one side, and a screw lock on the

other. This makes a very secure form of fastening. At the same time the mechanism of the annunciator is very accessible, and in case it is desired to change the lettering

on the drops this can be done with a minimum amount of trouble. This annunciator has gravity drops which are locked in position so that it is impossible for them to shake down by vibration; however, as soon as the circuit is closed the drop falls by gravity. It is particularly suited for houses, apartments, hospitals, etc., and can always be kept clean, as any dust or discoloration can be removed with a damp cloth. The case being made of steel prevents warping, splitting or twisting. The Northern Electric Company are Canadian distributors.

A Good Testimonial

We don't take in washing, but here's story on the sales department. The other week a lady called up and asked to have an electric washing machine sent up on free trial, as we were offering at that time.

An attendant went along with it, and he doffed his coat and got to work on the wash. In no time the work was done, and then milady called us up and said.

"Thank you so much for the washing machine. I was leaving to-night for Calgary and I could never have got my washing done. Will you please send up for it before 5 o'clock?"—B. C. Buzzer.

Denzar Lighting Units

A highly efficient lighting unit for offices, stores, factories, schools and public buildings—the Denzar—is manufactured by the Beardslee Chandelier Manufacturing Company, Chicago, and is shown in the accompanying illustration.

tion. The company call particular attention to the following features: (1) Housing of steel, white porcelain enameled; (2) Yoke of spring steel supporting metal holder; (3) Metal holder supporting reflecting dome and lower bowl; (4) Reflecting dome of opal glass, softens and distributes light; (5) Adjustable hanger for adjusting lamp without removing glassware; (6) Deflector diverts upward rays downward to working plane; (7) Upper part of bowl clear glass, protects lamp from dust and dirt; (8) Lower part of bowl white enameled glass, softens and diffuses light; (9) Air intake allows cool air to pass upward continually around lamp. The Denzar unit is distributed in Canada by the Perkins Electric Company.

Equator Toaster Stove

The illustration herewith shows the "Equator" toaster stove, manufactured by the Equator Manufacturing Company, Hamilton, Ont. It is a very ruggedly constructed ap-

pliance, built of nickel plated, cold rolled steel and rated at 550 watts. It is approved by the Hydro-Electric Power Commission.

Personals

Mr. Wills Maclachlan was elected one of the vice-presidents of the American Institute of Electrical Engineers at the annual meeting of the Institute held in New York, May 16.

Mr. F. I. Spielman, of Spielman Agencies, Regd., Montreal, agents for Griffiths Bros. & Co., London, British Aluminium Co., British Ever Ready Co., etc., is on a business trip to England.

Mr. F. T. Kaelin has been appointed chief engineer of the Shawinigan Water & Power Co. He was formerly assistant chief engineer, and joined the staff in 1902, coming to Canada from Switzerland.

Mr. H. Hulatt, manager of telegraphs, Grand Trunk and Grand Trunk Pacific Railways, Montreal, has been elected second vice-chairman of the Telegraph and Telephonic Division of the American Railroad Association.

Mr. Geo. D. Perry, general manager of the G. N. W. Telegraph Company, was presented with a cabinet of silver at the recent conference of managers and superintendents held in the Carls Rite Hotel, Toronto.

Mr. J. N. Lanphier has been appointed electrical inspector of the Collingwood district, succeeding Mr. R. R. Matson, resigned. Mr. Lanphier is a returned soldier and has been for some time assistant inspector in the Hamilton district.

Mr. F. W. Teele, vice-president and chief engineer of the Southern Canada Power Co., Montreal, has been appointed general manager of the Mexican Light & Power Co. and the Mexican Tramways Co. Mr. Teele will take up his residence in Mexico City.

Sir Oliver Lodge has been awarded the Royal Society of Arts Albert Medal in recognition of his work as the pioneer of wireless telegraphy. The medal was instituted in 1864 to reward "distinguished service in promoting arts, manufactures, and commerce." The presentation has been made by the Duke of Connaught.

The Electric Reduction Co., Buckingham, P.Q., are about to extend their dam, with a view of increasing the water power, in connection with their plant. Mr. J. B. McRae, of Ottawa, is the engineer. The contract has been awarded to the Foundation Co., Montreal.

A new sub-station is to be erected in the north part of the city of London for the supply of current to factories in that section.

Twin City Electric Club Meeting

A very enthusiastic and successful meeting was held in Kitchener at the Twin City Electric Club quarters on Tuesday, June 10, Mr. K. A. McIntyre was the guest of the Club and gave detailed information in regard to the affiliation of the local electrical contractors club with the National Association of Contractor-Dealers. Mr. McIntyre showed himself to be entirely familiar with the great benefits to be derived along this line and the prospects are very bright for such an affiliation, the members being quite enthused over the benefits to be derived, which they believe will well repay them for their association membership. The Kitchener contractors and dealers attended the regular meeting of the contractors' and dealers' Club in Brantford on June the 17th inst., where the prospective affiliation was further discussed.

The Twin City Electric Club has been in formation for practically three years, and during that time complete co-operation has resulted, to the great benefit of consumers, central stations and contractors, all differences, etc., being amicably and fairly adjusted, and the members feel that the time has been well spent and results obtained have more than justified the time and expense.

The President of the Twin City Electric Club, Mr. F. O. Ellis, expressed himself thoroughly interested in the promotion of like electrical clubs throughout the country and of clubs being associated under one head in a district which would comprise central Ontario. He feels that such an association could benefit the interested parties generally to such an extent that they would likewise become very enthusiastic over the results that would be obtained from such an organization.

It is the intention of the Kitchener Club to have a representative at the Milwaukee National Convention.

New Montreal Engineering Company

Monks, Manhard & Dawson, consulting engineers, agents and contractors, have opened an office at 813 New Birks Building, Montreal. All three members of the firm—Lt.-Col. K. C. H. Monks, C.E., Lt.-Col. W. E. Manhard, D.S.O., B.Sc., and Capt. F. M. Dawson, M.C., B.Sc., M.C.E.,—have served with the Canadian Engineer Corps overseas. Lt.-Col. Monks—who is now in England on business—was on the headquarters staff O.M.F.C., London, as director of Engineer Services and Quartering, and responsible for all technical details relating to leasing, contracts, building construction, and maintenance of heating, lighting and power plants in use by Canadian troops in England.

Statistics show that 25 per cent. of factory accidents are due directly or indirectly to poor lighting.

Messrs. Meldrum & Sterne have left for England, to open an office for the Shawinigan Water & Power Company in London.

Baetz Brothers Specialty Company, Limited, has been incorporated, with head office at Kitchener, Ont., and capital stock \$40,000, to manufacture and deal in electric fixtures and supplies. The principals of the company are Messrs. J. H. Baetz, C. J. Baetz, W. J. Flieschauer, of Kitchener; F. Anthes, of Montreal, and W. H. Beney, of Toronto.

The manufacture of glass pencil prisms is another German and Austrian industry which has been established on the North American Continent. Formerly we were entirely dependent on these European countries for the prisms, but now they are being manufactured in large quantities on this side, and can be obtained in Canada from Armour Bros. of Montreal.

Current News and Notes

Bridgeburg, Ont.

The Welland County Telephone Company, Bridgeburg, Ont., have taken over the stations of the Bell Telephone Company at Bridgeburg, Fort Erie, Ridgeway, Chippawa and the lines in the townships of Bertie and Willoughby. The Bell company will take over a small portion of the Welland Company's lines in Port Colborne and Humberstone. This action will render unnecessary considerable duplication of telephones in business houses.

Montreal, Que.

The International Electric Company, Limited, have been granted letters patent under the Quebec Companies Act. The capital stock is \$75,000, and head office, Montreal.

J. Ortiz & Company, electrical contractors, Montreal, Que., have registered.

The Victoria Electric Supply Company, Montreal, is among recent registrations.

New Westminster, B.C.

A new factory is planned for the manufacture of electrical equipment on Industrial Island, of New Westminster, B.C. The factory will be built by the Electrical Mfg. Co.

Niagara Falls, Ont.

W. P. Dixon, electric supplies, Niagara Falls, Ont., suffered loss by fire recently.

Peterboro, Ont.

The Hydro-electric Power Commission have been negotiating to purchase the dam at Lakefield owned by the Dickson estate. The estate has placed a price of \$200,000 on the dam. A more favorable price may be arranged by arbitration.

Portage la Prairie, Man.

A by-law authorizing an expenditure of approximately \$350,000 for the construction of a transmission line from Winnipeg to Portage la Prairie, Man., was carried by a large majority. The work will be supervised by the electric departments of both cities.

Toronto, Ont.

The Pierson-Wilcox Electric Company, a company incorporated in the State of Minnesota, has been granted a license to transact business in Ontario.

Windsor, Ont.

It is stated that the Hydro-electric Power Commission of Ontario have abandoned their announced intention of purchasing the lines of the Sandwich, Windsor & Amherstburg Railway. An increase in fares is considered very probable and this, it is thought, will so increase the value of the company's franchise that the Hydro-electric Commission could not purchase advantageously.

The Hon. Jules Allard, Minister of Lands and Forests for the Province of Quebec, in reviewing the policy of the Government in developing the water powers, stated that the construction of the St. Maurice dam had resulted in an annual profit, after providing for interest, redemption, and sinking fund. Mr. Allard said that it had been claimed that in Ontario power could be developed cheaper than in Quebec. The Government was open to conviction, and would change the system now in force if matters could be bettered, but he had gone into all claims, with engineers and accountants, and still believed that the system in Quebec was the best.

The entire holdings of the Renfrew Electric Manufacturing Company, Limited, have been purchased by the Renfrew Electric Products, Limited.

PHILLIPS' ARMOURED CABLES

A detailed cross-sectional diagram of a three-core cable. The central part shows three circular conductors arranged in a triangular pattern. Each conductor contains a cluster of small white circles, representing the strands of the conductor. The conductors are separated by a thin layer of paper insulation. This central core is surrounded by a thick, dark outer layer, which is the lead covering. The entire assembly is encased in a double-layered steel tape armor, shown as concentric rings.

Stop Advertising and You're Forgotten

"**H**OW long do you think your good-will is good for, if left to itself? The public has a short memory. Are you willing to risk its forgetfulness— even to invite it? Figure it out in dollars and cents. Can you afford it?"

ANNOUNCING

A New Emergency Power Plant.

Medium and high speed Sterling gasoline engines (which have held world's marine records for eight years) have been adapted for driving centrifugal pumps and electric generators. They are being used by many prominent pump manufacturers, coupled to Underwriters' fire pumps, and are installed in townships, villages, municipalities, department stores and manufacturing plants for fire protection. They are also utilized for emergency generator drives. The motors are admirable for either pump or generator operation as they develop rated power at 800, 1,000, 1,200 and 1,400 r.p.m. The construction is in 4, 6 and 8 cylinder units, 10 to 300 h.p.

Numerous units are employed in the United States and Canada. They are equipped for instantaneous starting for any emergency and will always furnish dependable power until the emergency will have passed.

A Time and Labor Saving Screw for Electrical Contractors

Robertson ^{Patented} Socket Head Wood Screw

In these days of high costs of labor and material, you want to save wherever you can. The Robertson Socket Head Wood Screws will save time, money and material. They are easy to drive—all you have to do is place the screw on the driver—it sticks there, enabling you to drive at arm's length if you wish. Indispensable for use in hard-to-get-at places, such as between joists, under floors or between narrow openings.

Let us prove our statements by sending a few samples and our prices.

We supply bits to suit any ratchet, also drivers in all suitable styles free with first order.

Strong Selling Features of Durable Daytons Mean Real Profit for Dealers

Illustrating Durable
Dayton No. 676

Six blade 12 or 16 inch
Oscillating Fan, con-
vertible to bracket
position.

Durable Dayton Fans are easy to sell and good to sell because of their quality—they mean satisfied customers and repeat orders—Dayton fans are sturdily made, for long, untroubled service. They consume less current and their square-end blades deliver more breeze.

The line is complete, including electric ceiling, desk, and wall bracket models for alternating and direct current, exhaust fans and water motors. Easily adaptable; all Dayton desk fans can be immediately converted into the wall bracket type.

Opportunity to "Cash In"

Demand is for quality now, stronger than ever before—Daytons have held the fan quality leadership for 26 years, the best fan for every purpose.

Durable Dayton dealers are given co-operation; sales helps and advertising that brings in customers and profits.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

Krantz Panel Boards

Safety

THE door is open to operate the switches, but no live part is exposed. A child or inexperienced person is, perhaps of necessity, called upon to manipulate the lighting. There is no danger when a Krantz Safety Panel Board controls the situation. A second and inner compartment which holds the live parts can only be exposed by the action of the electrician himself who holds the key to the second door.

Our catalogue explains fully the Krantz advantages and shows a multitude of reasons for using this board in your best work. Send for a copy.

**Give It
the
Emery
Wheel
Test**

**Spaulding
HARD FIBRE**

Put a sheet, rod or tube of Spaulding Hard Fibre in contact with a revolving emery-wheel. Note how slowly, how finely, how evenly it grinds down. Observe its compact, closely knit, horn-like composition that improves with age and will outlast the machine or product on which it is used.

A Universal Material

Its electric rupture is 200-400 volts per 1/1000 in. of thickness; tensile strength 10,000-20,000 lbs. per square inch; shearing strength 9,000-13,000 lbs. per square inch. It can be machined, sawed, stamped, bent, threaded, drilled and finished in many attractive ways.

Made in red, black and grey colors. Send for samples. Our Specialty Department is equipped to machine special parts to your own specification.

You Eliminate Needless Risk

when you install "Sterling" Rubber Insulated wire in that building of yours. Its guarantee of safety consists of many years of unusually successful and dependable service, and in the fact that it is specified and used by architects, engineers and contractors of many buildings of international importance, one of which is shown above.

"STERLING" Rubber Insulated Wire

stands for superior quality, which means the greatest economy and durability. It exceeds National Electric Code requirements to a degree that entitles it to be considered as a separate and higher standard of excellence.

When in need of rubber insulated wire it will pay you to get prices of "Sterling" Wire before placing your order.

Our nearest office will give you complete information promptly.

Rankin & Cherrill, 55 Hastings St. W., Vancouver, B.C.

ECONOMY renewable FUSES

are in greater demand than any other fuses because ever since their first appearance on the market their performance has proved them worthy of the trust placed upon them.

They are **accurately** rated—efficient in operation. They are **safe** in every respect—not sometimes but **always**.

As compared with the use of one-time fuses, they cut annual fuse maintenance costs 80%.

An inexpensive “Drop Out” Renewal Link restores a blown Economy Fuse to its original efficiency.

Economy Fuses and Links live up to their name. The economy they effect is considerable—too big for you to ignore. Besides, you will profit by the added measure of safety they insure.

Sold by all electrical jobbers and dealers.

A Continent-wide Service

Resurfacing
Small
Commutator

Are you still turning down commutators on a lathe while your equipment stands idle for several hours? You can keep commutators and collector rings in smooth running order simply by using the Ideal Resurfacer while machines are under load!

One man wrote us it took him six to seven hours to have a commutator turned down on a lathe—on trying the Ideal he found he got better results in one hour and equipment was not shut down one minute.

IDEAL COMMUTATOR RESURFACER

The Ideal is an abrasive block, not a natural stone that is sometimes hard and sometimes soft, and that clogs with copper dust, but a specially manufactured product of uniform density and cutting quality throughout. By applying it as illustrated upon commutators or collector rings while in operation a smooth surface is quickly produced that saves wear and tear upon brushes and equipment.

You save time, labor and expense. Hundreds of the largest concerns in the country are constant users of the Ideal.

In order that you may convince yourself of its value we will send you the Ideal on free trial for ten days. If you are not satisfied with it return it—the test will not have cost you anything.

This **SOLENOID SWITCH** has been adopted
by the Hydro Electric Commission

They use it for
STREET LIGHTING

Now the fact that it is used by the Hydro-Electric Commission is proof that it is all we claim for it. It certainly is not an experiment, by the fact that it is giving efficient service in many towns throughout Ontario, as well as the other provinces.

No springs, swivels or other complicated mechanisms to give trouble. They close magnetically and are opened by gravity assisted by the tension of the laminated copper contact. All arcing is taken up on the carbons.

Increase the efficiency of your system and decrease the cost of installation by using our Type 17 H.E.P. Solenoid Switches, which are suitable for any frequency on multiple circuit or D.C. Series circuit.

Reduce Distribution Troubles and Expense

in these Five ways—

- Equip to handle “trouble” without costly cable or line cutting.
- Eliminate expensive “temporary” repairs.
- Install cable-end sealing devices.
- Stop extended service delays.
- Make every circuit interconnecting without cable or line cutting.

IT is the purpose of G & W distribution specialties to obtain maximum distribution **economy** for a minimum of **cost**—it is the purpose of G & W Engineering Service, with 15 years' experience for a working back-ground, to see that you do get just that.

Nowadays **preventable** waste is almost the same as deliberate destruction. G & W distribution specialties plus G & W application service can help you eliminate many costly, untimely distribution troubles. Ask us for the solution of your most troublesome distribution problems!

Have you received new Catalog No. 10? Contains Valuable illustrations and drawings for every Central Station Engineer

True Recording Instruments

Esterline meters known throughout the technical world for their accuracy and mechanical perfection.

The illustration shows one of the new style Graphic Meters, which is placed in an aluminum case with a glass face. The clock has an eight-day lever movement controlling the chart which is six inches in width and twenty-six feet long. A special inking device has been arranged for the marking of these charts. The holder will contain a supply for eight days. The ink is drawn through the tube to the pen by capillary attraction.

These instruments are ideal for power stations, sub-stations, industrial and isolated plants for recording load curves, voltage, current, and power factor. The value of a true station load curve cannot be overestimated.

Adjusto-Lite
A FARBERWARE PRODUCT
TRADE MARK

It Clamps Everywhere

Patented in U. S. and Canada

Every Home, Office and Store In Your Town Needs Adjusto-Lite

And you can sell them Adjusto-Lite. Because it fills the need for a strong clear light in many places where the regular lighting is insufficient.

Simply show your customers how Adjusto-Lite **clamps everywhere**—to desk, shelf, counter, bed, mirror, etc. How it throws a clear pleasant light just where light is needed—and they will buy Adjusto-Lite because **they need it**, and will pay the reasonable price.

Many of our customers will come to you for Adjusto-Lite because they read about it in the Literary Digest, and other big publications which carry our strong advertising.

Send for our assortment of six lamps. Display them in use on desk or table. They'll sell! It is a quality product for quantity selling. No breakages—no trouble. Every lamp guaranteed by the House of Farberware.

Adjusto-Lite Carries a Good Profit for You—40 per cent.

And it is a quality product through and through. Made in solid brass, statuary bronze or nickel. Finely finished. Compact, weighs little, easily carried about. Sold complete with 8-foot of silk cord and Bryant push-button socket. Guaranteed five years. Individually packed in display cartons for easy selling.

PRICES TO DEALERS

Brush Brass Finish, \$3.00

Statuary Bronze or Nickel, \$3.25

Terms: 2/10, 30 days net, f.o.b. N.Y.

NATIONAL PRODUCTS

SHERARDIZED

SHERARDUCT

The Rigid Steel Conduit with both surfaces Sherardized and Enamelled. Rust Proof and Acid Proof. Made of a high grade spellerized mild steel tubing.

Write for Bulletin 50

ECONOMY

BLACK ENAMELED

ECONOMY Black Enamelled Conduit is made of the same high grade spellerized mild steel tubing as **SHERARDUCT**, the only difference being in the protective coating. In an enamelled conduit there's none better.

Write for Bulletin 50

FLEXTUBE

Interwoven — Seamless — Non-Collapsible. Inseparable and Double Compounded. Easy to fish and every foot of every coil can be used

Write for Bulletin 151

FLEXTUBE

We cannot tell you *all* about *all* National Products in this limited space, but we want to call your especial attention to certain features of **FLEXTUBE** Double compounded, Non-Metallic Flexible Conduit.

It's the original seamless interwoven non-collapsible, non-metallic flexible conduit with the "roller-bearing" interior. There's absolutely no waste; every foot of every coil can be used, and it's so easy to fish that it's a pleasure for the wiremen to use it. That makes it profitable for the contractor, and its quality is such that the best interests of the owner are served. Note the construction. The seamless interwoven tubing compounded; then the protecting outer braid, also compounded—a double compounded tubing which is satisfying to those who insist upon the highest quality. Place your order for your requirements with your jobber; specify by name—**FLEXTUBE**.

*British Material
Canadian Workmanship*

The C. & H. Meters have long held the premier position for their accuracy, simplicity and scientifically correct construction.

Besides being absolutely the best instruments you can install for reliability, they represent a combination of Canadian and British production. With the war ended many of the obstacles of obtaining raw material from Britain have been removed, and we are now in a position to make old time prompt delivery.

A Time and Labor Saving Screw for Electrical Contractors

Robertson ^{Patented} Socket Head Wood Screw

In these days of high costs of labor and material, you want to save wherever you can. The Robertson Socket Head Wood Screws will save time, money and material. They are easy to drive—all you have to do is place the screw on the driver—it sticks there, enabling you to drive at arm's length if you wish. Indispensable for use in hard-to-get-at places, such as between joists, under floors or between narrow openings.

Let us prove our statements by sending a few samples and our prices.

We supply bits to suit any ratchet, also drivers in all suitable styles free with first order.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance.
Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is \$86.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

PRODUCTS

Quality First

Usually the ear is out of line with the trolley wire when it first makes contact with the hanger.

With Ordinary Hanger—

the ear must be backed off—

which leaves a loose joint between ear and hanger.

With O-B Lock Hanger—

the ear is turned still further and makes a

tight, solid joint between lock hanger and ear when the latter comes in line with the wire.

That Spring Washer Does It

Tight, weathproof joint between every ear and every O-B Lock Hanger cuts your maintenance cost. With the ordinary hanger there is almost always a destructive see-saw action which sooner or later strips the sturdiest threads.

This never occurs with O-B Lock Hanger. In addition they have all the essential mechanical and electrical characteristics.

There are different sizes and types shown in O-B Catalog No. 17.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

Don't Overlook The Farmer When You Start That New Sales Campaign

The gradual extension of central station lines into rural districts and the recent rapid growth of the farm lighting plant industry have created a demand for farm motor service which is attaining huge proportions. The contractor-dealer who is not planning to go after this new business actively is overlooking his best opportunity for future expansion in his motor business.

On every farm there are scores of laborious tasks ordinarily done by hand, which can be performed quickly and with but little effort by electric motor drive. Because of this fact, every farmer becomes an immediate prospect for motor sales as soon as he has electric service available on his farm.

To enable dealers to go after this business a complete line of Robbins & Myers Motors have been developed for farm service. These motors are made for operation on the low voltage farm lighting plant circuits or the standard voltage alternating current central station circuits.

In addition to the standard types a special $\frac{1}{4}$ H.P. Power Stand Motor is supplied which can be carried about for use with the many light machines used about the farm and country home, such as the cream separator, churn, washing machine, grindstone, fanning mill, etc. The motor is mounted on an iron tripod base and is equipped with a brace rod which can be clamped to the driven machine for maintenance of belt tension. A three step pulley is provided which runs at 285 r.p.m., a back gear being provided for speed reduction.

Bulletins and prices on farm motors will be furnished on request. Attractive folders on motors and fans for farm service will also be furnished dealers with their imprint. Ask for samples.

No. 14

Labor Unrest Not Primarily Due to Need for More Money

During the month of May last the savings deposits in Canadian banks increased by \$37,000,000, or at the daily rate of \$1,200,000. During the year ended June 1st, 1919, savings deposits increased \$160,000,000; this in the face of Victory Loan subscriptions of nearly \$700,000,000 during this period, as well as other provincial and municipal issues.

The savings bank is looked upon, in large measure, as a barometer of the working man's economy. The present increase in savings would indicate, therefore, that the working classes, in general, are prosperous and also that they are profiting by our various campaigns on thrift. Coupled with the present labor unrest these larger bank accounts seem to show that it is not the actual need of more money that leads the workman to demand higher wages but rather the fact that he has had a little taste of saving, of getting a little bit ahead of the game and he wants more.

This feeling of independence that a savings account engenders is a fine thing for the individual but there is evidence that it has developed into a sort of intoxication in many of the trades which will eventually get them, and all of us, into trouble. The ideal of a capitalistic working class can never be entertained. The main reason is that they don't need capital. What the working man needs is such a fair payment for his labor that he can live in comfort and lay a little aside for the rainy day. If he spends money extravagantly or foolishly he is being paid too much. If he is able to build up such a

reserve that he loses his head and becomes independent and undependable, then, also, he is being paid too much.

The trouble with the workman, in general, today does not seem to be that he is underpaid. Rather he is in the position where he feels that he has capital at his mercy and he is making capital pay. He is in fact refusing to feed the goose that lays his golden egg. What will he do when he goose can no longer lay?

Canadian Engineering Standards Association

The Canadian Engineering Standards Association was formed early in the present year with the object of carrying out in Canada, for the benefit of Canadian industry, work similar to that done in England by the British Engineering Standards Association, which has proved of such great industrial value. The Canadian Engineering Standards Association is not a Government institution, although it is recognized by the Canadian Government. The members, who serve on its committees gratuitously, are qualified by their technical and industrial standing to represent the interests of manufacturers, engineers and users, and are nominated by such bodies as the Canadian Manufacturers' Association, the Canadian Mining Institute, the Engineering Institute of Canada, the engineering schools of the universities, the railway services, important industrial firms and the great purchasing departments of the Canadian Government. The Association has now been incorporated by Dominion Charter.

A sub-committee has been named with A. A. Dion, Ottawa, as chairman to deal with electrical matters, and already manufacturers, and large users of transformers and various electrical associations have been asked to appoint representatives to meet Mr. Dion, prepare a report and submit it to the Canadian Engineering Standards Association. A sub-committee has also been appointed for discussing the standardization of incandescent lamps, and further committees will be appointed from time to time.

Montreal Harbor Electrification

The Montreal Harbor Commissioners are proceeding with the electrification of the harbor railway and have received bids for the equipment. Eight miles of lines, totaling about 20 miles of track, are to be electrified, from Beaudry Street east to the terminals at Pointe aux Trembles. The western section of the harbor will continue to be served by steam locomotives. A sub-station will be built at Beaudry Street where provision will be made for two units. The plans provide for only one of these being installed at present; this will consist of a 1500 h.p. synchronous motor, direct-connected to two 500 kw. 1200 volt generators, connected in series. In addition there will be the usual switchboard and control equipment. The overhead catenary will be of the standard type. A new transmission line, with wood and steel poles, will be constructed to supply power to the sub-station. Provision is to be made in the same sub-station for an industrial load for the new cold storage warehouse to be erected at the east end of the harbor.

Attended the A.I.E.E.

The following Canadians attended the annual convention of the American Institute of Electrical Engineers at Lake Plaza: G. B. Smith, Belleville; A. E. Davison, D. McKenzie, H. C. Don Carlos, A. H. Hull, Ontario Hydro Commission; John Murphy, Ottawa; F. R. Ewart, Toronto; L. B. Chubbuck, H. B. Dwight, Canadian Westinghouse Company, Hamilton; S. E. M. Henderson, J. C. McFarlane, Canadian General Electric Company, Toronto; Wills MacLachlan, Toronto.

Canadian Electrical Association Convention at Alexandria Bay

Valuable Reports Presented by Sub-Committees—A. Monro Grier, K.C., President Canadian Niagara Falls Power Company, Re-elected President of the Association—Valuable Paper by Mr. F. G. Clark.

The C. E. A. Convention delegates may have found Alexandria Bay a little hard to get at but they unanimously voted it a first-class place to spend a holiday. The Toronto and Hamilton delegations arrived on Thursday morning and the eastern representatives came in during the afternoon. The convention proceedings did not open until Friday morning, so the interval was most enjoyably spent in renewing old acquaintanceships. A good dance hall made the evening pass all too quickly, thanks to a number of lady delegates.

The Friday's sessions consisted chiefly in an introductory address by the president, Mr. A. Monro Grier, K.C., and the presentation of reports by the chairman of the various committees. These are mentioned in more or less detail below. On Friday evening the delegates met together at dinner which was followed by a brief address from the president. Mr. Grier never displayed his unsurpassed command of the English language to better advantage and the delegates were delighted and charmed beyond measure.

On Saturday morning a paper was presented on the subject "Oxygen and Hydrogen as a Central Station Load," which had been prepared by Mr. F. G. Clark. Mr. Fredericks also addressed the delegates on "Service at Cost."

Saturday afternoon was taken up with a meeting of Class A members, when certain private matters were discussed and the officers elected for the coming year. The elections resulted as follows:

President, A. Monro Grier, K.C.
First vice-president, E. A. Dunlop.
Second vice-president, P. T. Davies.
Third vice-president, A. P. Doddridge.
Secretary-treasurer, W. Volkman.

Managing committee, C. S. Bagg, R. J. Beaumont, A. A. Dion, A. V. Gale, J. S. Gould, F. T. Kaelin, D. H. McDougall, R. B. McDunnough, H. R. Mallison, W. H. McIntyre, J. F. Neald, J. S. Norris, L. W. Pratt and J. B. Woodyatt.

Report of Committee on Prime Movers

Steam Power

In Canada, the plentiful supply of electrical energy supplied from Hydro-electric sources and the necessity of conserving the fuel supply of the country during the period of the war has turned the minds of all engineers and manufacturers to the necessity of economy in the operation of steam generating plants and the efforts of designers and operating engineers have been concentrated on improvements in this direction.

Considerable progress has been made in late years in the science of generating steam due to a better understanding of the combustion of fuel and the transmission of heat in boilers.

Mr. F. A. Combe, of the Babcock & Wilcox Co., in a paper entitled "Modern Boiler Practice" calls attention to the fact that though no radical changes in boiler construction

have taken place yet improvements have been developed in the arrangement of boiler heating surface due to more efficient furnaces, boiler settings and plant operation.

Present day tendencies favor high steam pressures and temperatures, concentration of power and large unit capacities. The shell boiler has been practically eliminated for this class of service and modifications have been made in the setting and rating of water tube boilers. Existing conditions encourage the use of boilers of high efficiency and rating.

The application of insulating brick in boiler settings is now becoming better understood. It is generally accepted that the walls of a boiler furnace should be built of as few different kinds of material as possible and walls should be well bonded and homogeneous. Recent tendency has been to build walls of solid fire brick.

In order to preserve the furnace side and bridge walls various expedients have been tried. What is required is a furnace lining capable of withstanding the high furnace temperatures and blow torch action; the constant heating and cooling effect and abrasive action of the fuel bed.

Ventilated walls, special refractory materials, steam jets on side walls and high temperature cements have all been used with varying success.

The present tendency is towards higher boiler ratings. One of the principal factors involved in high boiler rating is the coal burning capacity of the grate or in other words stoker and furnace design. Draft loss at high boiler ratings is an important item to be considered and the character of the boiler feed water may readily become a factor in boiler ratings.

We cannot attempt to treat this subject fully in this report. The local test as to whether a boiler is priming lies in the quality of the steam leaving a boiler or in the temperature of the steam leaving the superheater. A recording thermometer on steam outlet from superheater will indicate priming by sharp fluctuations on the superheat temperature curve.

Power dump grates and clinker grinders seem to be coming into use. The Westinghouse Co., and American Engineering Co., have these on the market as well as several other concerns.

The forced draft type of chain grate is now being used more extensively with success in burning low grade fuels high in ash.

Regarding meters, indicators and instruments general progress in their development has been normal.

Higher steam pressures have been tried out in one or two plants in the United States.

The Buffalo General Electric Co. have recently placed in service a plant operating at 275 lbs., boiler pressure, 275 deg., superheat giving a total temperature of 689 deg. F.

The Public Service Co., of Northern Illinois, have an installation operating at 315 lbs., boiler pressure, 225 deg. superheat giving a total temperature of 615 deg. F.

The general impression seems to be that the question of higher steam pressures is a boiler problem and that turbines

can easily be designed for operation at the higher pressures.

[A description of the Heine cross drum water-tube boiler was included in the report at this point.]

Steam Turbines

In recent years there has been a marked tendency towards the installation of units of large capacity and during the past two years there has been a marked increase in the U. S. in units of the horizontal shaft type of approximately 30,000 kw., capacity in order to meet the rapidly increasing density of the load. The Prime Movers Committee of the N. E. L. A. in their report for 1919, have included a list of large unit installations which is of considerable interest.

The main sources of trouble in large steam turbine units seem to be in the labyrinth packings and thrust bearings which are apt to cause excessive vibration of parts; the breaking of buckets, dangerous rubbing of stationary and moving elements which in extreme cases may result in permanent deflection of the shafts.

[Here followed a statement by the General Electric Co. with reference to turbine generators; also a copy of the report of the sub-committee on generators of the N. E. L. A. with reference to the matter of fires originating within the generator shell of turbo-generators of enclosed type.]

Water Power-Turbines

During the four or five years period prior to the war the manufacturers of hydraulic turbines made great strides in developing units of high efficiency and simple designs. This was primarily obtained through the introduction of the high specific speed single runner units. During this period a great number of low head plants were built using single runner units of larger size than anything previously attempted. During the last four years, however, the activities in hydro electric developments were greatly lessened and few new features in design have come out, although a certain amount of research work has been carried out the benefit of which should be realized in the near future.

Efficiencies of 92 to 93 per cent. of runners have already been obtained in several plants and we may assume that this is very near the maximum efficiencies that can be expected; but, in order to obtain a maximum over all efficiency of plants, hydraulic turbine engineers are now carefully looking into the design of all passageways from headrace to tail-race. Particular attention is being paid to the design and efficiency of draft tubes for high specific speed runners. The tendency is towards the use of deeper draft tubes with the idea of making the turn from the vertical to the horizontal direction at lower velocities than was previous practice.

It is also generally realized that improvements can be made in the design of intakes especially for low head plants.

There seems to be a difference of opinion as to the number and size of units to be installed in a projected plant; the tendency has been to look upon the water turbine as an almost fool-proof piece of machinery; consequently, plants have been equipped with as few and as large units as possible, thereby making considerable saving in first cost as well as operating expense. Considering, however, that the reliability of a unit does not only depend upon the water turbine but also on the generator and auxiliaries some designers of power plants incline towards comparatively small units with less chance of shortage of power in case of breakdowns. The question as to size and number of wheels to be installed in a plant must, of course, also be decided upon with regard to the transmission system and importance of continuous service.

Runners

The single runner vertical shaft units for low and medium head plants have proven to be of such a success that

practically all new plants under this category are now being equipped with this type of units.

Turbine manufacturers are constantly experimenting with higher specific speed runners in order to meet the demand from customers for large units operating under low heads. While a few years ago a specific speed of 100 was considered high, manufacturers claim today to be able to build low head units with a specific speed of 170.

Thrust Bearings

With the increase in size of large vertical water wheels and the consequent increase in weight of the rotating parts, the importance of satisfactory thrust bearings cannot be exaggerated and a great deal of progress has been made in recent years.

The General Electric Company, Schenectady, N. Y., have developed a spring-supported thrust bearing in an effort to overcome certain difficulties experienced in the operation of thrust bearings on this character of service. The main features of the spring supported thrust bearing is that it automatically adjusts itself to unequal loading due to inaccuracies in workmanship or in alignment. A distinctive feature of this bearing is that it will automatically adjust itself while in operation if there is a loss of alignment due to settling of the foundation or to other causes.

The bearing is not affected by wobbling of the shaft. The rubbing surfaces are in a bath of oil and the quantity of oil

We have not enough high-class retail establishments. We must make it easier for people to buy electrical appliances.—W. L. Goodwin.

circulated from an outside source depends on the losses and the cooling conditions. Water cooling coils may be installed in the bearing housing which will reduce the amount of oil and in certain sizes of bearings at low speed, no circulation of oil from a source outside the bearing housing is required.

The salient features of the G. E. spring supported thrust bearing are:

A thrust collar keyed to the shaft which transmits the weight of the revolving parts to the rotating ring of the bearings. This rotating ring has a smooth rubbing surface and is so designed that a rapid circulation of oil is maintained.

There is also a stationary ring, the upper surface of which is the stationary rubbing surface of the bearing. This ring rests on springs and to insure flexibility it is made thin and has a radial saw cut through one side.

Sufficient springs are provided so that the stress is only about one half that usually used and the deflection under load is about 0.1 in.

Cooling coils are used to carry off a part of all the heat generated between the rubbing surfaces of the bearing. Centre pins hold the springs in position. An oil well tube is provided which forms the inside annular wall of the oil chamber and is welded to its supporting ring. Dowel pins keep the stationary ring from revolving.

Two of these bearings have recently been installed in the Cedars Rapids plant of the Montreal Light, Heat and Power Consld., in connection with the last two 10,800 h.p. units, and have now been in operation for some months and have given entire satisfaction.

These bearings are designed to sustain a load of 550,000 pounds during continuous operation of the generating units at a normal speed of 55.6 r. p. m. A good grade of lubricating oil well filtered and free from water or entrained air and at a temperature not greater than 43 deg. C. maintained at a

level above the sliding surfaces is used and under these conditions bearings can carry 600,000 lbs. without injury.

The cooling coils are placed within the bearing housing beneath the surface of the oil and are of such length, number and size as will keep the temperature of the oil within the bearing housing under 45 deg. C. when supplied with water at 25 deg. C. under all conditions of normal operation. The bearings are capable of operating at a max. runaway speed of the unit, not exceeding 111.2 revolutions per minute of the shaft, for the space of one hour, and the temperature of the oil not exceeding 55 deg. C. The bearings are also capable of starting from rest and stopping as often as may be required by service conditions and are capable of operating at a speed of 10 r. p. m. for a space of one hour, without injurious heating of oil or bearings.

Bearings are designed to suffer no injury due to interruptions of water circulation for space of one half hour under otherwise normal conditions or for a space of 20 min. not exceeding 50 per cent above normal speed.

The general construction of these bearings is such as will allow the bearing all its parts to be removed from the bearing housing without disturbing the generator or water-wheel except by supporting the turbine shaft and generator by independent means provided and the removing of the thrust block keyed to the top of the shaft.

These bearings are the first ones of this size to be equipped with water cooling coils for circulation of cooling water instead of using oil circulation.

The Kingsbury thrust bearing has already been described to a great extent in many engineering periodicals and shall not again be treated in this report. It may be of interest, however, to the members to know that this type of bearing has been adopted by the Hydro-electric Power Commission of Ontario for the Westinghouse generators on the Queens-ton development. They are designed to carry a load of 900,000 lbs. at 187½ r. p. m.

Governors

No radical departure from standard designs of governors, mechanical or hydraulic, have taken place recently. The tendency has been in the past to specify quick acting governors in order to maintain a constant voltage. This tendency may lead to serious troubles, particularly where the turbines are connected to long penstocks, which are not protected by relief valves or surge tanks.

Designers are aware of this danger and considerable attention is now paid to this problem.

Troubles encountered in governor systems, such as corrosion of pipe lines and governor parts, where water is used as operating fluid, are being met by the introduction of soluble oil barium hydrate and potassium bichromate into the operating fluid.

There still seems to be a difference of opinion among designers as to the advisability of using individual governor systems or to have all governors receive the operating fluid from a central pumping system. The latter system is, as a rule, the cheapest and when the necessary care is taken in laying out pumps, pipe lines, etc., very satisfactory from an operating point of view.

A noticeable improvement has taken place in recent designs of water turbines with regard to accessibility, thorough lubrication and easy cleaning of turbine parts. One of the important features of the single runner vertical unit is the easy removal of gate mechanism for inspection as well as the easy adjustment of guide vanes.

S. Svenningson (Chairman)
A. H. Wilson,
A. J. McDougall.

Report of Meter Committee

To the President and members of the Canadian Electrical Association:

Gentlemen:—

Your committee this year has decided to depart from the established precedent of the Association, and instead of preparing a report of a technical nature to present the following, with a view to opening a discussion.

In view of the fact that the greater part of the revenue of operating companies derived from the sale of electric power depends upon the accuracy of the electric meters, your committee this year has decided to discuss the present commercial methods of re-calibrating and government inspection of meters. The accuracy of calibrating commercial meters depends fundamentally upon the maintenance of accurate standards. At present the standard meters are calibrated from time to time in various isolated laboratories, either maintained by the operating companies themselves or by the universities, and in some cases by the government laboratories, and the frequency of testing these standard meters rests at the discretion of the individuals in charge of the meter departments of the various operating companies. It is well known that different companies have different equipment for the calibration and standardization of their various instruments, varying more or less in accuracy. We believe it would be very much to the advantage of the company members of the Canadian Electrical Association if, instead of each company maintaining a primary standard laboratory that arrangements be made whereby more use could be made of the beautifully equipped and very little used government laboratory at Ottawa, which we presume was equipped with surplus revenue from meter inspection, and therefore should be devoted to the benefit of the companies who supplied it. At present it is possible to send instruments there and have them tested, but as so little use is made of it by the public the routine for handling them with dispatch is not given very much attention. At the same time, we feel that this is not the fault of the government, but that of the companies for not having instituted arrangements whereby more use is made of these facilities. The use of this laboratory by all Canadian companies would not be practical owing to extreme distances from Ottawa. However, it might be possible to arrange that government inspectors with primary standards which are portable make periodic visits to the plants of the various companies and check their working standard. In making this suggestion we do not feel that we are asking the government for anything we are not entitled to, as the understanding has always been that the revenue derived from meter inspection was for the purpose of covering the expenditures in connection with inspection, and as the government blue book for year ending March 31, 1918, shows a surplus of revenue over expenditures of \$35,019.47, a surplus revenue such as this should not only permit of a reduction of rates, but also the establishment of a very complete system of government checking of secondary standards and cover the expenditure in connection with the checking in the laboratories at Ottawa of any standard meters required at a very much lower rate than at present exists.

It has been brought to our attention that there is a movement on foot by the Hydro-Electric Power Commission of Ontario to delegate the work of testing and sealing meters to the various provinces, thus taking it away from the Canadian government and incidentally, we presume, allowing the Hydro to escape from paying a tax which would be chargeable to competing companies. This, to our minds, would be a serious mistake, and we feel it our duty to object

strongly to any effort of this kind, and would suggest that this association should go on record to the government against it, as if the work were delegated to the different provinces the meter manufacturing concerns would be obliged to comply with numerous conflicting requirements, involving more or less unimportant details and the standards for the different provinces would most likely vary to such an extent that the meter manufacturers would find another reason for increasing the present high cost of integrating meters. At the same time, we feel that a determined effort should be made to have the Dominion Government improve their present system of meter inspection, as at the present time, besides being expensive, inconvenient and unsatisfactory, it offers very little protection either to the companies or the public, and we question if, outside of moral effect, it has any use whatever.

There is at present being organized in Ottawa a committee of standardization of engineering standards. They are undertaking the standardization of tungsten lamps and machinery and equipment of different kinds, and we believe that they should be petitioned with a view to having them arrange for a committee on the standardization of integrating watt meters with the view to having dials, connections, etc., made standard with all manufacturing companies.

During the past year there has been considerable discussion with regard to the changing of power circuits from twenty-five cycles to sixty cycles and vice-versa. One of the member companies who has changed from twenty-five to sixty cycles has succeeded at very small expense in altering his twenty-five cycle meters to operate at sixty cycles.

Your committee further recommends, in view of the importance of commercial electric meters and all questions appertaining thereto, and in consideration of the highly technical nature of some of these questions that a permanent committee be formed, the personnel of which should be one member from each interested operating company to constitute an organization for the collection and distribution of data and experiences in connection with electric meters.

In order that a means may be provided for the proper operating of such a committee consisting of members from different parts of the country, it is further recommended that it shall be considered the bounden duty of each member of the permanent committee to send a report covering all items of interest pertaining to the subject of meters to the secretary of this committee between the 1st and 10th of every month. It shall then be the duty of the secretary of this committee to edit these reports and combine them into one paper of more or less general interest, which may be presented at the annual convention, or, if desired, printed and sent to all interested companies before the convention.

With reference to the discussions of last year's meter committee at the annual meeting, we have been informed recently that as a result of this some of the meter manufacturers are contemplating putting on the market shortly a kv.a. meter.

Respectfully submitted,

E. J. Turley, chairman.
E. R. Spence,
P. S. Gregory,
Louis W. Pratt,
A. H. Winter Joyner,
Wm. Volkman,

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

Report of Committee on Electrical Apparatus

Turbo Generators

One of the side issues brought into existence by the sustained overloads carried during the war service is the question of fires, their origin and the best means of handling them, and in view of this a questionnaire was circulated by the Sub Committee of the N. E. L. A., early this year, giving the following results:

Some thirty companies reported 81 fires in the past five years, 21 fires equally divided between 60 and 25 cycle units, were specifically described occurring in units ranging from 3,300 to 35,000 kw. and from 2,300 to 13,200 volts.

About an equal number of fires appeared to have started within the insulation and external to the insulation. The greater proportion of fires external to the insulation seems to have occurred on 3 phase systems operating without a grounded neutral. Other causes are many, principally short circuits and grounds, with the remainder from mechanical causes, eddy currents, moisture, etc.

The consensus of opinion is that more frequent inspection and cleaning of the generators is very desirable and has a direct bearing on the liability to fires from sources external to the windings. Too many companies appear to trust the air washing devices for this work, but even with the best possible apparatus, air and grease creep in, fluff and dirt accumulate and conditions for potential fires exist. Good practice, therefore, would indicate periodical cleaning, and we would invite a full discussion on this point.

The grounding of the neutral of 3-phase systems solidly or through resistance, is rapidly becoming standard practice on both 25 and 60 cycle throughout the country.

Twenty-one of the thirty companies replying favor this method of operation; five operating with solid ground system, preferring to operate through resistance; three companies opposed the grounding of the neutral. The consensus of opinion seems to be that grounding is very desirable and, in addition to other advantages, has a considerable effect in the reduction of generator fires occurring external to the insulation of the conductors.

It is also rapidly becoming standard practice, particularly on large units, for the manufacturer to bring out both ends of each phase winding to the generator terminal board so as to permit the installation of current transformers between the terminals of phase windings and the neutral of the coils. The current transformers can be connected differentially with respect to the instrument current transformers in the leads between main oil switch and generator, so that in the event of a fault in the generator or its leads the balanced relay will immediately open the main oil switch, the neutral switch if closed, and, after slight delay, the field switch.

Twenty-four of the thirty companies reporting approve the installation of balanced relay protection and have adopted it as standard practice on all new generator installations and on older generators where the expense involved is not too great.

The modern type of turbo-generator is usually completely enclosed and the blower action of the ventilation is such that fires are apt to become serious and very difficult to extinguish. As in the case of most fires the time element is the main factor in controlling it, it is especially important to apply the extinguishing medium as promptly as possible, and as close to the seat of trouble as can be done without permanent injury.

This leads to the question of ways and means of fire

fighting. Water, steam and carbon-tetra-chloride are looked upon with favor, the standard ways of applying being to pipe these mediums up to the end bells and provide a stand by service.

Sub-stations

The outdoor type of sub-station is rapidly being adopted for both industrial and distributing purposes. Some companies are using self-contained out-door metering outfits, and report practically no trouble with them. Other companies are using small structures for switches and meters, while others are using all weather-proof apparatus.

The use of single-phase transformers for three-phase banks is still general, but in many cases, particularly in limited quarters, the 3-phase transformer is becoming more popular.

The general practice appears to be to install transformers of just sufficient capacity to carry the load and use water cooling and spraying for over loads.

For protection of customers' sub-station the practice varies from over-load relays on the main oil switch and fuses in each transformer to the practice of one large company in the Southern States, which treats transformers for 11,000 volts and upwards as part of the line, and provides no protection. We understand they think they are justified by the results obtained.

The automatic sub-station for direct current is growing in popularity. There are at present on d.c. railway service seven sub-stations of 1,000 kw. or over and 49 sub-stations between 300 kw. and 600 kw. All have been operating automatically or semi-automatically for some time, but apparently only one company operates automatic sub-stations in a 3-wire d.c. system. The d.c. automatic sub-station is here to stay, and engineers would do well to investigate it thoroughly as an economical proposition. We believe we are correct in saying that the manufacturers are prepared to produce reliable automatic apparatus when it is called for.

Automatic or semi-automatic a.c. sub-stations are in continuous operation, some being straight outdoor type and some part outdoor with switching and metering buildings. These substations usually consist of step-down transformers without out-door type potential regulators. In some cases automatic re-closing oil circuit breakers are used. These will open and close a circuit several times in a few seconds. After the third time of opening the circuit remains open until re-set by hand. Apparatus in automatic sub-stations should be more liberally rated than is customary and should be of the most rugged construction.

As sub-station apparatus, the rotary converter with a capacity of about 400 kw. appears to be about the upper limit in this class of machine. With the extension of the use of 60 cycle as a system frequency the 60 cycle rotary has come more into prominence, although at times on railway service flashing is troublesome. The use of flash guards, arc cooling devices and high speed circuit breakers is expected to bring them up on a par with 25 cycle machines.

Remote control, electrically operated d.c. circuit breakers are generally used on large rotary converters and in many cases remote control starting switches are also used.

Ventilation of Rotary Converters

For ventilation of large rotary converters most companies depend on the ventilation of the sub-station room; only one company operating a large number of rotaries in basement sub-stations uses a combined pressure and exhaust air system and has considered partial housing of the machine for artificial ventilation. Also one company brings air from the air chamber for its transformers through some spare ducts and, by means of baffles, directs the air around the machine. Blowers giving approximately $1\frac{1}{2}$ oz. pressure will usually have a capacity for both purposes.

In summing up the rotary converter practice we find that in large inter-connected a.c. transmission systems some companies using relatively small-sized converting units prefer motor-generator sets, but companies with large converting equipment of 200 kw. and above prefer rotaries on account of the efficiency and convenience over large range of loading.

The general policy of operating all banks of transformers and distribution feeders on one bus with an auxiliary bus provided is maintained. The capacities so connected are running considerably higher than 10,000 kva., and this brings up the question of the rupturing capacities of oil switches; in order to avoid considerable expense in changing over apparatus, as well as possible switch destruction, the use of reactors would seem desirable. Considerable difficulty exists in the determination of what constitutes the rupturing capacity of an oil switch; also the time element which should elapse before closing and re-opening the switch, as most oil switches are rated on a two-minute basis. This would seem to eliminate the use of automatic re-closing devices.

In view of the difficulties confronting the manufacturers in obtaining sufficient concentration of power for the testing of larger breakers and in view of the value which could be derived from evidence as to the successful or non-successful functioning of breakers under actual short circuits it is recommended that the operating companies make reports of such occurrences of importance to the manufacturers of the breaker, giving such data as will enable him to determine what service the breaker performed. Of such importance is this question that your committee would suggest co-operating with the switchboard sub-committee of the N. E. L. A., in view of using a standard report form which that sub-committee contemplates devising. The chairman of the committee by this co-operation should be in a position to advise the member reporting if similar troubles or successful results have been experienced with breakers of the same type.

Your committee at this point feel it desirable to call attention to the neglect which is usually the lot of the air break switch and would point out the danger of abnormal temperatures which are liable to be caused by oxidation creating bad contacts. The high tension air break disconnecting switch is particularly liable to this neglect, being usually placed out of ordinary reach and left to take care of itself year after year. We feel that these switches will repay the attention given them.

Your committee feel that in view of the work in connection with the standardization of constant potential transformers and the lead markings for the same that has been done by the general conference committee on technical subjects, representing the American Institute of Electrical Engineers, the National Electric Light Association, The Electric Power Club and the Association of Edison Illuminating Companies, and in view of the fact that these standards are being accepted by the manufacturers, that they would recommend the tentative adoption of this report as a basis for the establishing of these standards for Canada or the adoption of the report in toto if found desirable.

Your committee feel it is the duty of this association to assist in the establishment of international standards if they can be adopted by our country without sacrificing our interests and append herewith the report of the standards as revised in 1919 for your approval.

Report of Committee on Power Sales

President and members of the Canadian Electrical Association.

Lighting Sales

During the period under survey there have not been any marked developments in this phase of the work. The absence of development is probably due to the pressure of war work. However, one particular fixture is rapidly gaining a certain amount of popularity and is a form of semi-indirect lighting which is particularly interesting in that it allows of the use of Nitrogen-filled lamps for domestic lighting, thus making it of great interest to Central Station companies as a means of increasing load.

Industrial lighting, on the other hand, shows considerable development and probably for the same reason, pressure of war work in the extensive production of munitions. In certain places in England and the United States it has been found that surprising results have been obtained by the way of increased production due to correct and improved lighting.

For specific details as to the actual work done we would refer to the proceedings of the Illuminating Engineering Society, but would here emphasize this matter as being of the greatest value to lighting companies as a direct means of immediately increasing revenue.

Very little development has taken place in this field except the growth of the use of ornamental underground lighting systems, fed by armoured cables taking advantage of the flexibility afforded by the incandescent nitrogen-filled lamps.

The question of rates on long-term contracts made some few years ago is in some instances seriously affected to-day by the high cost of lamp renewals, so much so that it would appear in some cases that the systems can barely bring in a return sufficient to cover a small interest on the money invested, and some central stations are basing rates with lamp renewals as a definite extra variable.

In connection with daylight saving, one of the most interesting subjects for consideration during last year, it may be said that to-day the lighting companies are in a position of knowing the worst and that daylight saving, from the point of view of decrease in revenue, is, after all, not a very serious thing. At the outside, the effect on lighting earnings over a year does not exceed a figure of 5 per cent., which checks up very reasonably with the estimated reduction.

Power Sales

The sale of power during the period of consideration was, in the early part, more or less normal. However, there was not any very marked increase by the way of establishment of large plants, such as occurred previous to that time. The signing of the armistice, of course, seriously affected the sale of power, and to a less extent, the amount of power used.

With regard to the amount of power used, in almost every case where large systems are concerned it was found that the decline in load did not at all assume serious proportions previously estimated, and that in some cases where a wide service of large capacity was delivered the amount of power delivered was practically only reduced for the period between the signing of the Armistice and the end of 1918.

The present time is one of development, stabilization and return to pre-war conditions. Numerous projects covering a wide variety of productions, are under consideration, and

from the power sales point of view there is considerable work to be done. The immediate future holds a promise from the power sales point of view there is considerable in smaller blocks than during the war period, but covering a much wider range of products.

To meet this coming demand most of the larger power companies in Canada are either constructing plants or preparing designs ready to construct plants.

The use of the electric stove is more than ever rapidly increasing. The designs of the stove offered have not during the past year, to any extent, shown any extraordinary radical changes or new developments, except in so far as continuous and increased efficient service is concerned, such as is effected by an element having a longer life and slight modifications in structural design.

The question of the fact of an electric range load on a distribution system built for lighting is now rapidly becoming known, and to the minds of most engineers, is shown by careful load survey to be very satisfactory from the view point of diversity.

The average central station manager, until lately, was rather inclined to view the electric range as perhaps a good thing to have on the system in small quantities, but to a certain extent, feared what the result might be in considering that apparently a large range load would mean a tremendous expenditure in lines and transformers.

Practically, however, due to the diversity, the rapid installation of the electric range has not resulted in any such conditions as at first thought. The diversity has been found to lie between the limits of 10 and about 30 per cent., and for the average system having over 100 ranges connected the diversity factor will not exceed 15 per cent. The average demand for one stove does not often exceed forty per cent.

It is the opinion of this committee that if some means could be found whereby the cost to the consumers of the stove could be considerably reduced it would considerably increase the use of the electric stove.

Another point to be considered is that the range demand on a system seldom overlaps the lighting peak. This definite knowledge regarding the diversity factor of the range load cannot but result in the central station manager pushing the installation of electric ranges more than ever.

The question of the cost of a range forms an interesting study. There is no doubt there exists room for what might be termed the "Ford of the electric range business." and if a range could be sold to the central station to-day at about \$60.00 it would add a great stimulus to its use. This range could be sold to people of very moderate means, such as mechanics, factory workers, etc. There exists, of course, the need for the higher priced ranges and as time goes on we find that amongst discriminating buyers of more extensive means the higher price ranges are easily sold and are actually in great demand.

The business of selling electric stoves is still, to a certain extent, clouded by the fact that there does not exist on the market, to our knowledge, a water-heater that will give absolute satisfaction! The manufacturers of water-heaters, in some cases, seem to have done everything that can be done to cover the situation, but there are so many difficulties to be overcome, the question of impure water being probably the most serious and a trouble that we can hardly lay at the door of the manufacturers.

However, a heater has been designed to overcome this, known as the "Clampon" heater, in which the element is fastened directly to the outside of the circular hot water tank.

Synchronous Motors

Synchronous motors are rapidly coming into popular use, and in the opinion of this committee, rightly so, as the

judicious use of this type of motor both from the point of view of the power company and the consumer is a step in the right direction.

This particular type of motor is, of course, broadly, only practicable in the larger size of the motors, being perhaps more complicated from the operating point of view. However, their usefulness in this sphere of the work fills a great demand. A motor of medium, say three to five hundred horse power, has great value in correction of power-factor on a system of fair size where the power factor is of fairly high value, say about eighty, and, we may by this use easily effect an improvement of at least ten per cent., thus making existing generating or transformer equipment of greater value to the power company and proving likewise beneficial to the customer in freeing him from penalty for low power-factor under the penalty clause.

The practice of making rebates on the power charge by giving a bonus or arranging a sliding scale with the customer is sometimes resorted to. For example, a range of from eighty-five to ninety per cent. power factor may be taken below which figure the power factor clause operates, and above the higher figure the customer commences to receive rebate on his power charge.

This practice is hardly to be commended as in the average case of a contract of this nature the amounts of power are fairly large and the customer usually has miscellaneous equipment and can, in some cases, practically run his plant at unity power factor, a condition not often considered at the time of making a contract. In cases where a customer has to run of necessity in certain classes of manufacture a small steam plant, it can be readily understood what possibilities such a bonusing scheme offers.

The object of the penalty clause and the use of the synchronous motor is to bring the power-factor as near unity as possible and so make maximum use of all electrical equipment, but it is not primarily to be thought as a method of giving lower power-factor rates.

While talking on the subject of synchronous motors, we recommend the close attention of manufacturers to this subject with the idea of standardizing designs and reduction of cost.

One of the difficulties met with at the present time in connection with the propositions where a fairly large amount of transmission line work is involved is that the present high cost of labor and materials make resultant rates for power much higher than previous years, and when compared by prospective users with rates of a few years ago, do not appear to them to be at all satisfactory. Unfortunately at the present time there do not appear to be signs of any great relief from this situation.

In connection with transmission of large amounts of power over fair distances high voltages are now being given serious attention by engineers, and voltages of 200 kilovolts, and more seem to be going well within the range of construction and standardization. The same remark may be said of turbine and power generating units.

It might here be mentioned that 1918 saw the completion by the Shawinigan Water & Power Company of the longest transmission span yet constructed, this being some 5,000 feet between tower centres carrying a three-phase circuit with wires in horizontal plane fifty feet apart.

The subject of arc furnaces does not present any great advance from that indicated in our report made last year with the exception that a number of large size furnaces used in the manufacture of carbide and ferro-silicon, are continually being added. The arc furnace field, however, has recently seen the partial development of a three-phase furnace for the fixation of nitrogen, which promises well for the future.

R. J. Beaumont (Chairman)

Oxygen and Hydrogen—A New Source of Revenue for the Central Station

By Mr. F. G. Clark*

On the assumption that a diversity of loads is the first requisite of a central station, the next would be a high ratio between the average load and the peak load. The attainment of a high load factor with diverse types of load is one of the main problems of a central station management.

It is not my purpose to discuss this problem, but to set before you the facts relating to one specific proposition capable of smoothing out the rough curve of a variable load, and of filling the valleys between the peaks of the load at the generating plant. The electrolytic cell suggested for this purpose functions, with respect to power supply, the same as a storage battery on charge, and so long as its input rate equals the load variations, can be made to regulate just as well as the battery. The cells may be so controlled as to follow the rise and fall of a peak so that approximately 100 per cent. load factor may be maintained upon the generating plant if that is desired.

The value of regulation of the load curve is well understood by central station managers, but increasing the load factor introduces many complications, most of which are peculiar to each particular system and must be separately considered. I will not attempt a general discussion of these matters, but shall refer to one phase of the question, which can be viewed in a new light, the supply of power to street and interurban railways, and the electrified sections of steam railroads. Neglecting for the moment, the last mentioned, we find that whereas a decade ago practically all electric railways generated their own power, often at excessive cost, due in part to their very low power load factor, they are, to an increasing extent, becoming customers of the central station companies. The central station sells three phase, alternating current to the railway in bulk, and the railway converts and distributes it from its sub-stations. An annual load factor of 30 per cent, and a daily load factor of 40 per cent. is about the average for street railways. Mingled with the diverse loads of a central station, these factors may be equated to 40 per cent. annual and 50 per cent. daily, but this is about the best that can be done. Storage batteries would benefit the load factor, but cannot be considered in this connection, by reason of their 60 per cent efficiency and the fixed charges.

Electrolytic Cells

Electrolytic cells of the type here considered have been designed with special reference to operation where the electrical input is variable and subject to rapid and violent fluctuations.

The thermal efficiency of the cells previously used varies from 28 per cent to 33 per cent. with current flowing at the rate of .1 ampere per sq. in. of diaphragm surface between electrodes. That of the new cell varies from 25 per cent. to 35 per cent., with current varying from .5 to 4 amp. per sq. in. of diaphragm surface between electrodes.

The usual method of expressing cell efficiency is to ratio the actual voltage per cell with the decomposition voltage of water between platinum electrodes. This is not a true measure of efficiency, but upon this basis present cells with .1 amp. per sq. in. operate at 80 per cent. to 85 per cent. efficiency, and with 1. amp. per sq. in. at 40 per cent. to 60 per cent. efficiency. The new cell gives the following efficiency:

At .1 amp. per sq. in.	95 per cent.
" 1. " " " "	89 " "
" 2. " " " "	89 " "
" 4. " " " "	60 " "

*Chief engineer Toronto Power Company.

The installation costs of large-sized plants equipped with existing types of cells, including building, but exclusive of electrical generating or converting apparatus and compressors, will not be less than \$750 per kw. of electrical input, and will generally exceed \$1,000 per kw.

The installation costs of the new cells, including building, but exclusive of electrical apparatus and compressors, will, for similar plants, be approximately \$50 per kw. of the normal electrical input.

The efficiency of the new cell at its normal rating is about the same as that of the present cells, which is 80 per cent. referred to platinum electrode decomposition, or 30 per cent. thermal. By decreasing the current rate per unit of diaphragm to the normal rate of existing cells, the efficiency increases, and by increasing the current rate to double the normal rate, the efficiency drops to 60 per cent. dissociation or 25 per cent. thermal. The new cells may be operated at this high rate, though it must be understood that the cost of electrode and diaphragm renewals must be taken into consideration. Operation at twice the normal rate reduces the installation costs per kw. input by one-half.

Maintenance and Renewal Costs

We may assume that the maintenance costs on cells and building is, for existing cells, 2 per cent. per annum. The maintenance costs of the new cells depend upon the gas output, although skill in operating the cells has a bearing upon these costs. The results of two years of operation indicate the following.

		Percentage of total costs for maintenance and renewals	
When average rate is .5 amp. sq. in.		3 per cent.	
" " " " 1. " " "		5 " "	
" " " " 2. " " "		8 " "	
" " " " 3. " " "		13 " "	
" " " " 4. " " "		20 " "	

Interest, depreciation or amortization and taxes are taken at 10 per cent.

The attached sketch has been prepared to indicate the typical loads of a city of about 250,000 inhabitants.

The railway company generating its own power, would require four 3,000 kw. units. The electric light and power company, for its own uses, would require four 5,000 kw. units; if it were to supply power to the railway company, one additional 10,000 kw. unit would be needed. It may be taken as an accepted fact that the railway company's load can be furnished more cheaply by the power company than it can be generated in its own plant, so that the carrying charges of the railway plant are probably the determining factor in the arranging for a sale of power by the power company.

Looking at the railway curve, you will see that it might be possible for the power company to sell the railway requirements up to 7,000 kw., in which event their own plant would be in use only a few hours per day. It is doubtful, however, if this would produce any net saving over the purchase of all the power required. I might suggest that if hydro-electric power were being considered, then the steam generating plants would not be required except as stand-by reserves, or to carry the seasonal daily peaks.

While these and many other considerations have a bearing upon the question of purchase by a railway company, and sale by a power company of power for railway operation, it may well be some other factor that will turn the scale into a profitable undertaking for both parties, and my somewhat lengthy preamble brings us to this point.

Cost of Kilowatt-Hours

It is a well-known fact that kw.h. generated in a plant do not cost alike. The peak kw. h. cost the most, and the off-peak or night kw. h. the least. If the load curve were

a straight horizontal line, each kw. h. would cost the same as every other one; but even in this case, unless all of the kw. h. were used in the same way, their value for sale would not be equal. Let us suppose, for example, that the power company was able to sell to a user of power those kw. h. shown on the sketch as the cross hatched area. The effect of this would be to raise the load factor from 60 to 72 per cent., and in doing this the power company would hold control of the power delivery at all times. The kw. h. certainly do not cost the power company anything for generating capacity, and, if supplied to the railway company, nothing for transmission capacity. The cost, therefore, will be the coal, labor and maintenance costs attributable to those particular kw. h.

It is a well known fact that the operating costs of the kw. h. generated between 1 and 5 a.m. because of the low load on the plant, is greater than for the kw. h. on peak, so that if the night valley be filled up the extra kw. h. should not carry any fixed charges, and their total cost should ap-

Illustrating the use of 3000 kw. of electrolytic cells on combined electric load of a city of 250,000 population

proximate the operating cost of the peak kw. h. As a matter of fact it can be proved that they cost less.

Let us see how this works out by referring again to the sketch.

	Peak	Average	Total	Load Factor
Railway load	9,500 kw.	4,000 kw.	96,000 kw. h.	42 %
Light and power load	16,000 kw.	10,500 kw.	252,000 kw. h.	65 %
Combined load	23,000 kw.	14,500 kw.	348,000 kw. h.	60 %
Adding cell load	23,000 kw.	16,500 kw.	396,000 kw. h.	72 %

With coal at \$4.00 per net ton, and labor at 1919 rates.

	Fixed Cost	Operating Cost	Total Cost
Railway load	\$.0030	\$.015	\$.0180
Light and Power load	.0024	.010	.0124
(a) Combined load	.0020	.009	.0110
(b) Total load	.0020	.0075	.0095
(a) The fixed charge of the railway steam plant not included.			
(b) No additional plant required.			

It appears that the off peak power superimposed upon the plant costs \$.0075 per kw. h. If this off peak power can be so used that it will net the power company \$.0075 per kw. h. they can afford to sell to the railway at \$.01 per kw. h. As a matter of fact the sale would probably be at so much per kw. of peak per month or year, with an energy charge for

the actual energy taken, producing in a year a return equivalent to one cent per kw. h.

Selling D.C. to the Railway Company

It is suggested that the power company shall sell d.c. instead of a.c. power to the railway company, and take over the sub-stations for this purpose, charging for the d.c. power the equivalent of 1.25 cents per kw. h. to cover fixed charges and losses.

Having these sub-stations in charge, the power company should install electrolytic cells and operate them from the d.c. buses as off peak power users and regulators of load on the generating stations.

Let us assume that there are four sub-stations, each of 3,000 kw. capacity, and that in each the following cell installation is made:

1 electrolytic battery, 1,000 kw. normal.

1 oxygen compressor.

1 hydrogen compressor.

1 water still.

Fixed tanks, spare parts, etc.

3 installations, \$150,000.

These cells will average 66 per cent of the normal rate, but will at times be operating at nearly twice the normal rate

The costs per day would be:

Fixed charges on cost at 10 per cent.	\$41.00
Maintenance at 8 per cent.	33.00
Labor and materials	60.00
Power	43.50

\$177.50

The gas manufactured per day would be:

99.5 per cent. pure hydrogen 336,000 cu. ft.

99 per cent. pure oxygen 168,000 cu. ft.

Cost of both gases 35.25 cents per 1,000 cu. ft.

Liquid air oxygen 97 per cent. pure costs \$2.00 per 1,000 cu. ft. and at 1,800 lbs. pressure, in cylinders, sells at from \$12.00 to \$20.00 per 1,000 cu. ft.

Electrolytic oxygen, when impure, contains hydrogen, a heating gas, giving out over 300 heat units per cu. ft. when burned in the air. When oxygen is used for welding or cutting, 3 or 4 per cent. of hydrogen is not a disadvantage, and simply results in less oxygen per unit of holder capacity. Hydrogen as an impurity in oxygen, beyond 10 per cent. produces a mixture which tends to become explosive, and becomes more dangerous as the hydrogen content exceeds 10 per cent of the volume.

Impurities in Oxygen

Liquid air oxygen, on the other hand, contains nitrogen, an inert gas, as its impurity, and this impurity is seldom found less than 3 per cent. Although this impurity tends to render the oxygen more and more safe to handle as its content increases, it renders the oxygen less and less valuable in much greater proportion. Exhaustive tests in welding and cutting with the oxy-acetylene torch indicate that oxygen gas containing two per cent. of hydrogen is 20 per cent better than oxygen gas containing two per cent of nitrogen.

When both gases, or rather, the total gas, costs 35.25 cents per 1,000 cu. ft. the oxygen alone will cost \$1.06 per 1,000 cu. ft. In that case the hydrogen is free, and can be sold for any price that will cover the expenses of sale.

The present use of oxygen gas in the U. S. alone exceeds 5,000,000 cubic feet per day, or 1 cu. ft. per 20 inhabitants. If the use were uniformly distributed according to population, a city of 250,000 people would require 12,500 cu. ft. per day. The use of oxygen is confined to manufacturing towns and cities, and particularly to those engaged in certain lines of manufacture.

The requirement of a city of 250,000 may not exceed 12,500 cu. ft. and it may be in excess of 500,000 cu. ft. per day. A canvass of the manufacturing establishments will soon disclose the actual needs, and the use of oxygen will increase as its cost decreases.

Hydrogen cannot be used for welding iron or steel, although it can be used to a limited extent in the welding of other metals. In the oxy-hydrogen torch it is an excellent cutting agent, and when a great deal of cutting is necessary, as in a steel fabricating plant or a shipyard, should replace the oxy-acetylene torch for this purpose.

Uses of Hydrogen

There are a number of present uses for hydrogen, and its future in the arts is an array of possibilities almost staggering the imagination. It is used in the hardening of oils and fats, as in soap works. It is used in glass blowing as a heating agent. It is used in the laboratories of manufacturing plants and colleges as a reducing agent.

All of the above uses are predicated upon hydrogen at a cost of from fifty cents to two dollars per 1,000 cu. ft.

If the plant we have been considering were treating hydrogen as the product and oxygen the by-product, the cost of hydrogen would be fifty-three cents per 1,000 cu. ft.

When both gases are saleable products to the capacity of the plant, their respective costs should be based upon the relative values of the two gases, in which event oxygen would always be worth at least twice as much as hydrogen, and the costs would be, for oxygen fifty-three cents and for hydrogen 26.5 cents per 1,000 cu. ft.

A company manufacturing oxygen, with hydrogen as a by-product, may dispose of the hydrogen in bulk in two ways, reserving the privilege of withdrawing any portion that can be sold at higher prices to manufacturers who can use it in their processes.

Hydrogen burns in the air to form water, and for every 1,000 cu. ft. of hydrogen thus consumed, 305,000 heat units are liberated.

The heat standard for illuminating gas is 585,000 heat units per 1,000 cu. ft. and this gas is made by the retort or water gas process. Coal gas, as usually made, will absorb from 5 to 15 per cent of hydrogen, without lowering its heat value below standard. Water gas, when burned, liberates 308,000 heat units per 1,000 cu. ft. and at present costs for coal and labor in a plant supplying a city of 250,000, can be made for from 15 to 20 cents per 1,000 cu. ft. We may, therefore, take 15 cents per 1,000 cu. ft. as the value of hydrogen gas, delivered to a gas company.

Hydrogen as a Heating Fuel

Hydrogen gas may be used as a heating fuel, and be burned under boilers or replace gas in the heating appliances of manufacturers, or, by suitable changes in existing apparatus, be burned in retorts and circulated through the heating coils or radiators of the heating system of a building. The hydrogen must economically replace coal or gas when used as a heating agent. When 600 b.t.u. gas is used, the hydrogen has a value one-half that of the gas.

Where coal is used, the situation is complicated by consideration of space and labor saved, coal and ash handling eliminated, general cleanliness, and where soft coal is used, freedom from smoke.

I consider that the gas has a minimum value of twelve cents per 1,000 cu. ft. where hard coal, costing \$10.00 per net ton, is used, and a value of seven cents per 1,000 cu. ft. when soft coal, costing \$4.00 per net ton, is used.

The price for use in heating buildings will depend largely upon the results obtained and the value held by the purchaser of the many factors having a bearing. In connection with a lighting and power contract and the replacing of an

isolated lighting and heating plant, the gas may have a value of forty cents or more per 1,000 cu. ft.

Work is in progress relating to the development of processes for the production of large quantities of hydrogen, based upon the electrolytic cell and the use of larger quantities of hydrogen in the production of standard marketable products. The work has advanced to a point where I am warranted in asserting that the electrolytic production of the gases oxygen and hydrogen will shortly be of considerable import to industry in general.

Prospects are Good

In a statement of this kind which must necessarily be concise, I can do no more than hint at the possibilities, as much of the work we and others are doing along the lines of research and development have not yet reached the final or commercial stage. I can only suggest that the prospects are very good for the announcement of one revolutionary proposition in the near future.

The foundations of the revolutionary change are the gases oxygen and hydrogen, and the keystone of the arch is the electrolytic cell.

The Toronto Power Company is preparing a bulletin containing full information regarding the cells and detailed information will be given to those interested. I might add that the Toronto Power Co. operates one of the hydraulic plants on the Canadian side at Niagara Falls, and a steam plant at Toronto. The combined peak load capacity of its plants is 185,000 h.p. In 1915 the company established a research department, having for its purpose among other things, the increasing of the load factor of its system, and incidentally of its revenue.

Finding that the manufacture of the gases oxygen and hydrogen by the electrolysis of water was a promising proposition and that there was no apparatus on the market suitable for use on a large scale, having regard to the economic features, the research work was at first concentrated upon the development of a type of cell which would meet the requirements.

The result of this development is a type of electrode construction permitting operation at high current densities and high temperature. Cells of this design have been in operation at the company's Toronto plant for over two years, having, in this time, fully demonstrated their commercial practicability.

The value of the electrolysis of water to the Toronto Power Co. will consist of the sale of oxygen and hydrogen at prices sufficient to cover the costs and carry a reasonable charge for the electric power used by the cells. As the company has an annual load factor of 50 per cent. the possibilities are tremendous, providing there is a market for the gases. There is idle potentiality for the manufacture of one billion cubic feet of oxygen and two billion cubic feet of hydrogen annually. This is more than the annual use of oxygen in the U. S. and Canada, and many times the annual use of hydrogen.

Transportation costs limit the radius of economic supply from a central plant, and this disadvantage increases as the price of the gas at the point of use decreases, so that both gases would have to be used at or near the point of manufacture. This company contemplates using the gases in manufacturing processes, which also have been developed by its research department, and information regarding which will be given out from time to time.

I think we have had an over-abundance of engineering knowledge and a lack of good commercial sense.—W. L. Goodwin.

Report of the Committee on Accident Prevention

During the war, although companies well realized the great need for the conservation of human life, due to the depletion of men for service overseas, yet they felt in some instances where it could not be perfectly proven that certain arrangements would materially assist in the saving of life, that the money and labor were not available for the carrying out of these otherwise laudable schemes. With the signing of the armistice, and, as we hope, the signing of peace within a few days, conditions have materially changed, and this Association might well look forward to carrying into very active operation some of the schemes that have been found to have merit in the prevention of the loss of life or limb to the employees of the electric companies. Some of the more important points that have been taken up by your committee might be classified under the following sub-titles:

Insulated Handles

Your committee wishes to draw to the attention of the association the extreme hazard in allowing men to use tools with insulated handles that are purchased from various manufacturers. This insulation is oftentimes depended upon for the protection of life where it is more a case of good luck than good management that a fatality does not result. Your committee would recommend to the association that, so far as possible, tools with insulated handles be not used except for very high voltages where special tools are required, but that dependence be placed upon rubber gloves tested according to specifications that will appear hereafter.

Classification of Reports of Accidents

For the past few years the National Electric Light Association has requested their members to report accidents on a form prepared by the association to headquarters. These reports are then compiled and statistical information prepared therefrom. This information is of inestimable value to member companies in seeing where most of the accident loss has occurred in the past, and so be prepared for the preventing of similar loss in the future. Your committee would recommend that similar forms be prepared by the Canadian Electrical Association and company members be requested to report accidents to the Canadian headquarters, the statistical information from which could be prepared and submitted to your association. At the same time the information being prepared in a similar way to that used by the N. E. L. A. would be conveyed to the N. E. L. A. to assist them in presenting more complete data. Copy of report of N. E. L. A. attached and marked "Appendix 1."

Rubber Glove Specification

For some years past the committee of the N. E. L. A. has been working on the question of the preparation of a specification for "the purchase, testing and care of rubber gloves for service on high voltage apparatus on circuits not exceeding 3,000 volts to the ground." Your committee has collaborated with the N. E. L. A. committee, and submits herewith, marked "Appendix 2," such a specification. Your committee would recommend that these specifications be adopted by this association and used by the Canadian member companies.

Specifications for Linemen's Belts

Similarly with the case of linemen's belts, we have collaborated with the N. E. L. A. committee, and a tentative specification has been prepared, copy of which is attached, together with blue print, and marked "Appendix 3". Your committee would recommend that these specifications be

Follow These Instructions Even If Victim Appears Dead

I. FREE THE VICTIM FROM THE CIRCUIT IMMEDIATELY

Quickly release victim from current, being careful to **avoid** receiving a shock. Use any **dry non-conductor** (rubber gloves, clothing, rope, board) to move either the victim or the conductor. Beware of using metal or any moist material. If necessary, **shut off current**.

II. INSTANTLY ATTEND TO THE VICTIM'S BREATHING

1. As soon as the victim is clear of the conductor rapidly **feel** with your finger **in his mouth** and throat and remove any foreign body (tobacco, false teeth, etc.). **If mouth is tight shut, pay no more attention** to it until later. Do not stop to loosen the patient's clothing, but **immediately begin actual resuscitation**. Every moment of delay is serious. Proceed as follows:

(a) Lay the patient on his belly, one arm directly **extended** overhead, the other bent at elbow and with **face to one side**, resting on the hand or forearm, so that nose and mouth are free for breathing (see Fig. 1).

(b) **Kneel straddling the patient's hips** with knees just below the patient's hip bones or opening of pants pockets; place the **palms** of your hands **on the small of the back**, with fingers spread over the lower ribs, the **little finger just touching the lowest rib**, the thumb alongside of your fingers; tips of fingers just out of your sight, as in Fig. 1.

(c) While counting one, two, and with **arms held straight, swing forward** slowly so that the weight of your body is gradually, but **not violently** brought to bear upon the patient. (See Fig. 2.) This act should take from two to three seconds.

(d) While counting three, immediately **swing backward** so as to remove the pressure, thus returning to the position shown in Fig. 3.

(e) While counting four, five—**rest**.

(f) **Repeat deliberately** twelve to fifteen times a minute the swinging forward and backward—a complete respiration in four or five seconds. **Time with your breathing**.

(g) As soon as this artificial respiration has been started, and while it is being continued, an **assistant** should **loosen any tight clothing** about the patient's neck, chest or waist. **Keep patient warm**.

anted on Application

Fig. 1

Fig. 2

Fig. 3

2. Continue resuscitation (if necessary four hours or longer) **without interruption**, until natural breathing is restored, or until a physician declares rigor mortis (stiffening of the body) has set in. If natural breathing stops after being restored, use resuscitation again.

3. **Do not give any liquid by mouth until the patient is fully conscious.** Place ammonia near the nose, determining safe distance by first trying how near it may be held to your own. Assistant should **hit patient's shoe heels** about twenty (20) times with a stick or something similar and repeat this operation every five minutes until breathing commences.

4. Give the patient **fresh air**, but keep him warm. When patient revives **keep him lying down and do not raise him.** If doctor has not arrived, give patient one teaspoonful of aromatic spirits of ammonia in a small glass of water if he can swallow.

5. Carry on resuscitation at **closest possible point to the accident.** **Do not move patient** until he is breathing normally without assistance. If absolutely necessary to move, he should be placed on a hard surface, such as a door or floor of conveyance. **Do not stop or interrupt resuscitation for an instant.**

III. SEND FOR DOCTOR

If alone with victim, **do not neglect immediate and continued resuscitation** in order to call a doctor; start at once, the first few minutes are valuable. If other persons are present, send one of them for a doctor without a moment's delay.

An up-to-date list of doctors, with telephone numbers, is posted close to this chart.

The prone pressure method of artificial respiration described in rules (Section II) is equally applicable to resuscitation from electrical shock as well as cases of suspended respiration due to drowning, inhalation of gas, smoke or fumes or to other causes.

or rigor mortis (stiffening of the body) sets in.

used by member companies as a tentative specification and criticisms and reports of attached be reported to your committee, so that more information can be obtained before a definite specification is adopted.

Co-operation for Safety Work

Your committee has had brought to its attention by one of its members, the very successful work of the Hamilton Electric Safety First Association, composed of the Hamilton Hydro-Electric, Dominion Power & Transmission Co., Bell Telephone Company, C.P.R. and G.N.W. Telegraph Companies, Hamilton Fire and Police Departments. By this association dangerous points on the various overhead lines in the City of Hamilton were brought to the attention of the officers of the proper companies, and where possible the difficulty was rectified. We attach hereto, marked "Appendix 4," a report by a member of this committee, together with other data, and would recommend to the association, where possible, the adoption of this scheme in other cities.

The bulletin of the N. E. L. A. has a section devoted to the work of accident prevention, and your committee would direct the attention of the member companies to this section of the bulletin. Data is presented there and short articles pertaining to accident prevention in the utility field, and it is hoped that such information will be read and put into practice where possible by your companies. This is practical information, written by those in utility work, for the information and guidance of men like situated.

Reunions and Sick Benefits

The National Electric Light Association at their Atlantic City convention saw fit to instruct their officers to appoint a committee to look into those most important employee relations pertaining to pensions, sick benefits and other welfare and economic lines for the benefit of the employees of the electric companies. In these times, when the newspapers and other press are full of problems of unrest, particularly that applied to relations between the employer and employed, it is not necessary for this committee to point out to you the seriousness of the situation, but we would respectfully recommend that the Canadian Electrical Association take ample means whereby their member companies, and particularly the executives of their member companies are kept fully advised as to the best methods for solving this most serious problem, and where your committee can most help it will be glad to do so if directed.

Educational Publicity Methods

In the report of the Accident Prevention Committee to the N. E. L. A., they made a very full and complete report in connection with education and publicity methods in connection with accident prevention. Your committee would direct the attention of the member companies to this report.

It is very complete and well warrants the reading, particularly of executives of companies.

Goggles

It has been found that some member companies do not know where to find the goggles for the protection of their men that they require. For general information, goggles for the protection of the eyes of workmen from electric flash can be obtained from A. H. Hardy & Co., 10 South Wabash Avenue, Chicago, Illinois. They are called the "Harco Safety Goggle," and if fitted with Noviolenz, will protect the eyes of workmen from the ultra-violet in an electric flash. Your committee would also recommend that member companies see that their men are equipped with suitable goggles for the protection of the eyes from flying chips of steel or concrete when doing any chipping or drilling of these materials. These goggles can be obtained from a number of reliable goggle manufacturers, and if member

companies are not able to obtain the suitable goggles, information will be supplied from your association headquarters.

Your committee has been giving particular attention to the question of resuscitation methods for electrical shock, and has kept in touch with the work being carried on in the United States. Without further comment we would recommend that this association formally approve "the rules for resuscitation from electrical shock by the prone pressure method," as issued by the N. E. L. A., in booklet and chart form, copy of which rules are attached and marked "Appendix 5." We would further recommend that this Association make arrangements to print the rules and the accompanying chart over the name of the Canadian Electrical Association for distribution where found desirable in Canada. For your information these rules have already been approved by the Hydro-Electric Power Commission of Ontario by the Association of Municipal Electric Utilities of Ontario.

Your committee feels that it has done very little during the year, but has attempted to present before you some of the more important points in connection with the work of accident prevention. These points may appear to deal with the more physical side of the work, but in previous reports your attention has been drawn to the fact that without sincere co-operation and active participation in the work of accident prevention, from the highest official of the company, down to the newest employee, successful accident prevention is impossible.

(Signed)

Wills MacLachlan, Chairman,

Report on Overhead Lines

Mr. A. A. Dion made a verbal report on "Overhead Lines." Practically the only work his committee had undertaken was in gathering information on outdoor sub-stations in connection with which a questionnaire had been sent out. Regarding the use of bare versus insulated wires for 2200 volts and under, Mr. Dion quoted the following opinion of one the member companies:

"Re bare wire for line use under 2200 volts. It has never been the practice of this company to use bare wire for city distribution and although it is generally understood that the insulation on the wire, especially after it has been baked out, is no adequate protection for 2200 volts, it is useful in the erection of the lines so as to avoid mechanical injury and also from coming in contact with live lines already placed.

"Our company's rules provide that all lines are normally considered alive by our men and work done accordingly. Lines are only treated as dead when known to have been killed properly, and the proper clearances given. In order to show differentiation between primary and secondary lines, lines of 2000 and 4000 are erected in porcelain insulators, while low voltage lines are on glass insulators.

"Use of both bare and weatherproof wire would necessitate carrying two classes of wire in stock as well as on repair and construction wagons. In city work the primary is only a small part of the distribution system and it would be still necessary to supply insulated weatherproof wire for all service work.

"In outlying districts where primary runs are long and service connections few it would likely be considerably more feasible to use the bare wire."

Mr. Dion gave it as his own opinion that while ordinary weatherproof triple-braided insulation is not altogether effective and linemen should treat all wires as alive, still the insulation is some measure of protection in dry weather and he favored its use on city streets.

The Contractor-Dealer

W. L. Goodwin Discusses Every Phase of Electrical Merchandising. The Apostle of Co-operation at His Very Best at Niagara Falls Convention. Evidence that His Seed, Sown with Such Care and Skill During the Past Two Years, is Bearing Fruit. The Address and Discussion Practically in Full

Perhaps one reason we have been deficient (and this applies particularly to the representatives of central stations, whether they be publicly or privately owned—the principle is the same in both cases) is that we assume the attitude of an ordinary merchant and imagine we have a product that the public will rush out and purchase simply because it is offered at a low price. That is not so. The technical nature of the product we sell, whether it be energy or merchandise, the newness of the product and the almost total ignorance thereof on the part of the purchasing public, should convince us with a little thought and study that no cheap, price-cutting methods will accomplish the ends we are striving to obtain. We must sell our product. If one were to make a trip throughout Canada he would perhaps find 75 to 80 per cent. of its homes unwired, and that percentage would carry even in some of our larger communities, proving conclusively that we have not sold the electrical idea to the general public. There can be no question, particularly in the province of Ontario, that you have offered the product at a low enough price! You have offered it almost without profit, and in some cases, I dare say, without profit, and still you have not persuaded anywhere near 100 per cent. of the people to use the product you are endeavoring to sell.

Intensive Methods for the Industry

An analysis of your rates would probably prove that much of your consumer business is taken at an absolute loss, and still the consumers have not flocked to your offices and demanded this product of energy or appliances at the low price at which they are offered. It is proved that right throughout this continent the product we have to sell must be sold by intensive methods. Aside from the fact that we have something to sell and that it should be sold at a profit, whether publicly or privately owned (as I will attempt to prove to you later on), something of a technical nature of which the public are largely ignorant, we must agree that to sell anything requires intensive methods. Then why not employ those intensive methods in our electrical industry? In other words, we must organize ourselves to present our commodity to the public in an understandable way, so that they will benefit by what we have to offer. Apart from the fact that we have something to sell, there is a greater responsibility upon the electrical industry than upon any other single industry. I contend that our industry offers a greater opportunity for the development of a country and of all humanity than that offered by any other industry. In other words, if Canada was thoroughly saturated electrically there would come opportunity for the development of your country.

Convenience of Electricity Induces Spread of Population

Our industry will perhaps do more to break down the great centers of population and spread it evenly over a greater area than any other dozen industries combined. In

the United States (and it must be so in Canada—or will be so in time) we are facing a serious situation due to the building up of these great centers of population. The attractions they offer to the public make life on the farm desirable, and today you can find throughout the United States, and I dare say throughout Canada, papers literally filled with advertisements for farm help and no response! In the evolution of things we can go back and by an analysis of our past experiences we can anticipate the conditions which will exist a decade hence unless something is done to spread the population of the country more evenly over the land. People flock to the centers of population because of the easy conditions of living, because of the facilities for obtaining employment, and many other inducements that are offered in the great cities. The electrical industry is the only industry which is in a position to offset those inducements and to place the farmer in the position where he can enjoy everything enjoyed by the city dweller. By reason of the centralization of power in the large cities factories congregate there, which has made the situation much worse, and with the exception of electrical energy the transmission of power over large areas would be almost impossible, because of the prohibitive cost of so doing. In our industry we can deliver power where it can best be used, and in addition to delivering power, all the other conveniences that accompany it. There is no longer a necessity of

Mr. W. L. Goodwin, the apostle of co-operation in the Electrical Industry.

locating factories in great centers of population because of the expense of power. Power can now be supplied throughout the land just as cheaply as it can in the large centers, to a reasonable degree. Therefore the electrical industry is going to be the means of changing the whole situation throughout the land, and nothing can make the "back to the land" movement more attractive. We must spread the people back over the land, because after all, the production in the industrial centers is not the kind of production that makes for prosperity. The farmer is the only real producer, and when we cut off the farmer everything must cease.

Fallacy of the "Bargain Sale" Method

We are passing through an era in the United States and Canada today in which it is no longer possible to induce men to farm. There is too much labor required for the compensation given. The electrical industry, however, is in a position to change the whole situation. But going out to the farmer and offering him electrical energy at one cent a kilowatt means nothing to him. He does not understand relative values. He cannot conceive of kilowatts at one cent paralleling wheat at \$2 per bushel. He is not interested in kilowatts per bushel, but is only interested in making a profit on the product he purchases; and the fact that foreigners are not utilizing the products we have to sell proves conclusively we have not employed the right method in selling our product. We have adopted the "bargain sale method" and have reflected that idea from the department stores, never realizing that the bargain sale method only represents about five per cent. of the sales of the department stores, and very often represents from 1 per cent. to 2 per cent. profit. On the train last night Mr. Chase mentioned that he fell for one of those bargain sales, only to find that the bargain sale price was enhanced by about 25 per cent. over the regular price for the rest of the month.

Lack of Commercial Sense

A little knowledge is a dangerous knowledge, and we have had too little knowledge in the electrical industry. From the standpoint of the central station I think we have had an over-abundance of engineering knowledge and a lack of good commercial sense. As an example I might cite a man who goes to a good college and acquires an engineering knowledge and comes out of the college and goes into the central station or into the commercial field. If he goes into the commercial field he will invariably drift into one form or another of the lighting industry. Why? Because there is something scientific or technical about it. He immediately starts to sell light on a scientific basis! Now, imagine talking to the average housewife about illumination on a scientific basis. She knows and cares nothing about it. Illumination is not the thing we want to sell to the housewife. We want to sell something which will make the housewife's work easier. We want to sell labor-saving appliances and devices, particularly in view of the scarcity of servants in these days, and in view of the very reasonable doubt that in the future the servant will be with us any more. My wife wants something to save labor. She understands lighting. You cannot sell my wife, nor any other man's wife, by saying to her: "Here is a flat iron at \$2.75," or "Here are kilowatts at 1½ cents." She wants somebody to go up and explain the virtues of those particular appliances, and not only does she want to know the virtues of those appliances and how they are going to affect her daily work, but she particularly wants to know what kind of an instalment basis she can purchase them upon.

Sell What Product Will Do

The product we have to sell cannot be sold for cash in any great quantities, as is proved in the sale of the washing machine and vacuum clean-

er, and other labor-saving devices. That has been proved in over 90 per cent. of cases in the United States. In the case of the washing machine we have had an increase in price of from \$75 to \$150, and still there has been a tremendous increase in the purchase of that commodity on the part of the consumer, because we have learned to employ intensive selling methods. We are not talking price to the consumer; we are telling what the product **will do**, rather than what it costs, and after all, prices are relative. The public soon get to know that the Ford automobile is worth so much money, and Ford is selling as many automobiles today as he was three years ago, in spite of the increase in price; the price of the Ford is compared with the price of some other car. We proved that conclusively in California, where we had a per capita consumption of \$5. In those days we employed every conceivable cut price and vindictive business method in order to put our product over on the people, and we were able to get away with an annual per capita on appliances of about \$5. Finally somebody conceived the idea that that was not the way to sell our product, and that we should get together, organize and advertise and put up a sufficient margin of profit to those interested to justify the selling expense. We tried that scheme for about three years and the per capita consumption rose to \$30. By proper advertising, display and solicitation we convinced the public that we had something they wanted. You have to employ about the same methods in Canada. You have assumed that the way to put over the electrical idea was to offer your products at a low price. That is particularly true in the case of your merchandise, and also applies to the sale of energy. What does it amount to? The energy consumed in an ordinary home, using all the appliances they may, amounts to \$3, \$4, or \$5 a month. What difference does it make whether it is \$2 or \$5? You do not stop to figure your pleasure in an automobile by the number of gallons of gasoline consumed. In other words, the automobile has been sold with the idea that it is something people want, and they will make sacrifices in order to purchase an automobile.

A Fair Price for Product

With the proper effort we can sell the same idea to the public electrically. We can convince them that the thing we have to sell is worth so much money. Do not let us talk in technical terms of kilowatts. It is all right to talk about cost of production when you approach a man in a factory for the purpose of selling him power in large quantities. In his case you can reasonably expect that he will comprehend your meaning, but not so in the case of the consumer. We must employ the most modern, intensive methods of selling our products, and we have not done that. I dare say that 3, 4, 5 or 10 times the amount of energy can be sold in Canada. What is the use of taking the public into the secrets of the electrical industry as to the relative merits of public or private ownership? And, after all, who cares? The publicly or privately owned plant can do the job, and do it right for the public. In one community it may be public ownership and in another community it may be private ownership, but both private and public ownership will prosper depending upon the attitude of the public, and the attitude of the public is not going to be favorable simply because we offer the product at a low price. If we get a fair price for our product we can afford to employ the very best means of marketing it.

Plants, Public or Private, must be Self-Sustaining

Let us take the publicly owned central station. Bonds must be sold. The public will purchase the bonds so long as they have confidence in the property, and their confidence in the property will be measured by the ability of the men financially and in every other way. We can fool the people

over a short period of time by eliminating from our accounting methods proper charges for depreciation and a lot of other things, and at the end of 15 years we can scrap the plant and go out for a new bond issue and get a lot of money to start over again. That, however, is a temporary proposition, and after a time the people are going to give it up, and the financing of public ownership property on any such basis must sooner or later result in disaster. Every recognized sound method of accounting employed either in private or public ownership should be applied. You should set up your proper reserves and operate your property at a profit. If you do that you have ample funds to take care of this tremendous field of exploitation. You cannot keep running to the public simply because you are a publicly-owned property and ask them to buy bonds to provide funds to exploit the industry in undeveloped fields. It seems to me that reserves should be set up to take care of exploitation. You cannot afford to operate a utility with a tax on the entire public when only a part of that public participate in the thing you have to offer. It is unfair to operate a street railway at a loss (assuming it is a publicly-owned street railway) and absorb the loss in a form of taxation covering a lot of people that do not use the street railway. It is unfair to operate a lighting company at a loss and call upon the public generally to sustain that loss when only 25 or 50 per cent. of the population utilizes the electrical energy. Those who utilize a product should pay for it, and therefore every operating company, whether privately or publicly owned must be self-sustaining. It is just as much to the interest of the publicly-owned plant to see that the privately-owned plant is self-sustaining and a proper rate allowed. The point I am trying to make is this, that after all there is no difference internally in the trade between the position of the operator of a privately-owned plant and the position of the operator of a publicly-owned plant. Their problem is the same—to serve the people. If the people desire to take over the plant we in the electrical industry, who know values, should be willing to set up a fair price and take the property over and operate it if that is what the people want. If they do not want it we need not concern ourselves.

Electrical Industry Used as Political Weapon

I think there has been too much mud throwing in the electrical industry, particularly by politicians who use the electrical industry and public ownership as a means of carrying an election day, and I do not think we men in the electrical industry should permit our business to be used for such purposes. We have a greater service to render mankind than simply to make grandstand play out of our electrical industry and use it as a political weapon.

We should be fair to one another. That applies in the central-station branch of the industry, and applies between the manufacturer, the jobber and the contractor-dealer. The greater the number of contractor-dealers you have operating in your community and conducting well-kept, high class, retail electrical shops, the greater number of appliances will be used by the public and the greater amount of electrical energy will be used, and the greater service will be rendered to the public, and that is, therefore, your responsibility as public servants to give the public the thing they want. What they need today is an easier means of buying electrical appliances and a more thorough knowledge of the thing we have to sell. We have not enough high class retail establishments—whether they be operated by the central station, the jobber, the contractor-dealer or the manufacturer is immaterial, the more the merrier—but we must make it easier for people to buy electrical appliances. We must properly display our product and not talk in technical terms of watts consumed and load per kilowatt, because that is not what

the people are interested in. The labor of a day's washing under the old method as contrasted with the new method is no basis of comparison in cost of energy consumed, and it does not matter if your rate is 1c, 2c or 3c. The same remarks apply to cooking. If we sell the electrical appliance on the basis of convenience in cooking we ought to be able to get more money for the thing. We are a poor lot of business men if we go out to sell an electrical cooking appliance, with all its convenience and cleanliness, and find it necessary to undersell the coal man! There is something wrong! We should try to find out what the cost is in the case of coal, wood, and other means of obtaining heat, and we should get as close to that cost as we can, but we must not try to undersell our product.

Present Problem is a Commercial One

The antagonism between groups (and it has prevailed in Canada) has been due largely to ignorance of our problem. The fact that we have struggled primarily with engineering problems is responsible. Our industry has been in charge of engineers. We have had to undertake this great water-power development and the solution of all these engineering problems, and the commercial end of our business was of little consequence. That is financially proven by the condition of many of the public utilities. They show that we have not had sufficient commercial talent behind the enterprise. Now we are calling for a higher degree of intelligence from the commercial side of the business. We are calling for a new type of men in the electrical industry, a real commercial man that can go out and properly present our product to the public. If you analyze the articles which appear in the press (and have been in our technical papers) you will find a strain of commercialism hitherto absent. You will find that the largest percentage of space in the ordinary trade press is devoted to commercial problems. We have solved the engineering problems. We can go down to the Falls and take away 20,000 or 50,000 horsepower, as may be required, without difficulty. Our engineers understand how to do that, but the problem is to sell the product after it is produced. We need not worry about the engineering problem any more, the engineer has solved his problem, and the great problem of the future, in the electrical industry, is a commercial one. Bear in mind that in Canada, as well as in the United States, you have not reached five per cent. of your potential market. You have still 95 per cent. of the road to cover. Is it the road of engineering? No, it is the road of commercialism. It is a road of popularization, of intensive selling. We cannot hope to travel that road by bargain sales or while friction between the various groups exists and unethical policies on the part of the manufacturer, the central station, the jobber and the contractor-dealer persist. An answer to your problem cannot be found by the utility man, the manufacturer, the central station, the jobber or the contractor-dealer alone, because of the interlacing of the electrical industry. You cannot come down here and start the wheels and turn out kilowatts and have them used. Somebody must manufacture wires and appliances, and somebody must build the houses to put them in.

Make Electrical Industry an Ethical Business

Go into a restaurant and see if you can find a waiter serving the beginning of the meal and another waiter coming along when it is about time to hand out the tip! Each man knows his place and keeps it. In the medical profession, if you are a doctor's client and right in the middle of your case you decide to discharge that doctor and employ another one you will find great difficulty in getting another doctor to take your case. Just try it once and see what will happen. He will want a thousand and one reasons why you should desire to change, and before he will accept your case he will go over and talk the matter out with his brother doctor

whom you have discharged. Conceive of such ethics in the electrical profession, an electrical contractor having a client and serving him well and faithfully and another electrical contractor saying "I will have to talk this over with Bill Smith before I take this job." Can you conceive of the condition where there are two central stations in a community either privately or publicly owned—in some cases in the United States we have two privately-owned companies and sometimes one privately and one publicly-owned company and in another case two publicly owned companies. The central station man's idea of success is to employ every means he can to steal a customer away from the other fellow, very often knowing he is not going to give as good service as the customer is then receiving. Why, all of our engineering talent and college training is wasted when we get into business. What do we gain by it? We are not told and not paid to do it in that way, and we know as men that we should not do it in that way. Why do we do it? We are not working on a commission basis. We are not compelled to go out and perform the acts of a thief.

Getting at the Causes of Friction

I assume this group before me are real business men. Supposing I ask you what you are doing as business men to bridge the friction between capital and labor, what would you reply? What are you actually doing? Are you going out and meeting these people and talking to them and trying to understand their language and their problems? And if you understand them and there is any merit to their case, are you willing to sit down and talk these things over and try to find a solution, or are you going to be fool enough to set yourselves up and, exercising the power that Germany thought she could exercise, try to put the laboring man in this country down? Is that our job? There is something labor wants, and anyone in close touch with labor knows what it is. It is not money. Anyone who believes labor is organized simply to get higher wages is absolutely wrong, and has not sensed the pulse of the working people. The working people want a new relationship and a new kind of treatment on the part of the employer. They want to sit down and talk about things which interest them. They are not concerned in the profit of the factory—that is to say, how much profit the factory makes above a reasonable profit—but what they want to know is that they are going to have permanent employment and be treated like human beings with red blood in their bodies and families in their homes, and to receive a wage sufficiently high to meet the cost of living and permit of provision for a rainy day. Are you going to ignore these things? That is what has been done in the electrical industry, and it is the job of somebody to go over the country and bring out these facts that produce friction in industry, either between employer and employee or between group and group, or between business and government, and to get at the fundamentals which are causing the trouble and ascertain the solution thereof.

Let me outline the Goodwin Plan and enumerate the planks thereof.

The Goodwin Plan

A campaign of education conducted principally through trade papers, trade organizations and other channels, to co-ordinate the various interests in the electrical industry and to bring them together in harmonious action, so that there may be established retail distribution of electrical materials at fair prices to the consumer, and at a fair profit to all parties taking part in the transaction.

The basis of the plan is:

1. That each individual owes a responsibility to the organization representing his branch of the industry.
2. That the organization owes a similar responsibility to its members.
3. That each organization representing each branch of the industry owes a responsibility to all other organizations

in the industry, all to the end that all problems may be discussed, having in view the interest of all, thereby providing a basic plan for more adequately and efficiently serving the American public, resulting in an extension of the activities of our industry to the great undeveloped field before us.

Objects of Plan

Intensify development in present fields. Extend the industry to undeveloped fields. Develop greater efficiency in industry.

Procedure

1. Bring together the various interests in the larger cities, cause them to formulate a plan to extend the work to the smaller towns and cities of each state.

2. To accomplish this, committees should be appointed from each of the four divisions of the industry forming local committees charged with the duty of making a study of local problems and co-operating in their solution.

3. Individuals comprising these committees will report their activities to their national associations, causing their national associations to take similar national action, looking to the solution of national problems.

Results

To produce harmony and develop co-operation between manufacturers, central stations, jobbers and contractor-dealers.

To produce greater efficiency in the distribution of manufactured products.

To increase per capita consumption of electricity, apparatus, devices and supplies.

Establishment of high-class stores.

Decrease in costs of conducting overlapping trade associations, and saving of personal time incident thereto.

Create a more favorable public opinion.

The planks of the Goodwin Plan are as follows:

1.—A strong representative association of electrical contractor-dealers (retailers) and urges all interests to lend immediate assistance to this end.

What are the fundamental things we must do? We must organize. You have your Association of Municipal Electrical Engineers. Develop it and make it a better and stronger organization, and invite the groups in at all times to hear your discussions.

Helping the New Organizations

There has just been formed Associations of Manufacturers and Jobbers in Canada. Let us all put our shoulders to the wheel and help those organizations along. They are new-born babes and are going to meet with all the troubles that infants meet with. The baby is going to stumble and skin its nose and get into backyards where it doesn't belong and do a lot of other fool things all new-born babes will do, all because they must get experience. You cannot tell this child anything about the experience of the father. He just wants to look over the precipice and fall down once or twice to see how it feels. So to keep this new-born babe out of trouble let us all help.

Similarly with the contractors, who have recently organized. Let us help them, too. These three organizations need development, and if the men who are operating public utilities throughout Ontario or Canada will not put their shoulders to the wheel, who will? Of course, I know you are doing everything you can, but for fear that there may be one man in the group who cannot see the justice or advisability of doing something to help these other organizations along, I say these words.

There is a real responsibility delegated to you as technical men and commercial men to develop this industry, and here are three new-born babes that need your help. Let us see how we are going to help them. We must build them up and tie them together. You should have in every community in Canada a good strong electrical association, with everybody in the industry meeting together and talking over local problems, and then tying these local organizations up to one Dominion-wide organization where you can get to-

gether at some other period and talk Dominion-wide problems.

2.—Each division of the industry should prepare a code of ethics outlining its own functions, relations and responsibilities to each of the other divisions of the industry.

It is a very simple matter to prepare a code of ethics. The central station man should be able to come right out and say "Here is what we do," and spread it broadcast so that the men in the trade will know.

3.—Each division of the industry should establish a code of practice, outlining its methods, policies, etc., in dealing with other than divisions within the industry.

Too Much "Junk" on Utility Bills

Can you conceive of anyone in the central station coming out with a little pamphlet stating the electrical idea in simple, understandable language, so that Mrs. Housewife can appreciate it? We seem to surround the whole electrical idea with mystery. My wife received a set of bills for gas, electricity and water, and it would take the best accountant in this room to figure them out. There is too much junk put on the average utility bill. You have to sit up all night to understand the thing. All the housewife is interested in is "\$2.40"; that is all she wants to know. So many kilowatts at the last reading and the next reading is of no interest to the housewife. Send her the bill for \$2.40 and don't talk about a lot of kilowatts. If you have any space on the bill put "Have you an electric iron?"

Can you conceive of a condition where the central station would put a simple little tag on its meter or in the house and tell the public "When you buy a lamp for this house buy it at 115 volts" or "110 volts," and tell them why. Have we ever attempted to explain to them the analogy between water and electricity? A woman knows if she turns on the water tap so much she gets so much water, and if she turns it on a little more she gets a little more water. Down at Hot Springs a little while ago Mrs. Goodwin asked me to purchase a travelling iron, and I bought a 110 volt travelling iron in a nice case and gave it to her and told her to connect it to the socket, and went out to play golf. I came back three hours later and found her in a nervous fit, and said "What is the matter?" and she said "This says 220 volts and you told me never to put 220 volts on a 110 volt circuit."

"A Lot of Damned Jackasses"

A woman cannot get that stuff at all. Then, of course if she tried to connect it in any ordinary place she just would not get it connected at all. There are just as many kinds of baseboard receptacles as there are electrical men in this room. Mrs. Brown buys an electric flat iron and takes it home and it fits right into the plug she has in the house. Next week she buys something else and goes to plug it in and she jabs and jabs and shoves, and what she says and thinks about electrical men!!! Talk about a lot of brainy electrical men! We are a lot of damned jackasses. Here are a lot of college men and technical men trained in an industry, and yet they go out and sell 150 different kinds of receptacles to a lot of women and children and wonder why we have not popularized the use of electrical appliances. It is all very fine for the engineer. His wife says "I cannot connect it," and he says "That is all right, that is a G.E. plug," and goes and gets another plug and fixes it up, but his wife sits there and looks on and thinks. We must start a campaign all over the land and rip all these plugs and receptacles out of every home and put in standard plugs, just as we took out the T.H. and Westinghouse and all the other sockets and picked out one that was standard, with the result that now you can screw in a lamp anywhere. Soon we are going to scrap all these voltages and have one

voltage, and some day when the engineers get together they will scrap these thousands of different frequencies.

4.—Improvement in merchandising methods, better display, and the encouragement of more retailers, by urging present contractors to open retail stores, thereby enlisting the support of central stations and offering a broader and larger outlet for manufacturers.

That really needs no explanation. A visit to electrical shops all over the world will convince anyone of the unsuitability of the methods that have been employed. We put in a fine display of material and then sit there and wonder why people do not come in and buy it! How do you expect them to buy it after what I have mentioned to you? The product must be well displayed and clearly marked. I went into the Washington Power Company's place at Spokane on Decoration Day, where I saw fine show cases and lots of product in them. I said to the manager: "I happen to know that is an electric egg boiler, but my wife would make 2,000 guesses and never guess what it was. Why don't you put a little sign on it and let her and other housewives into the secret?" In a window in Baltimore I found another example of the same sort of thing. A contractor down there opened a fine retail store. He remarked that it was not making the progress expected. I said "How long have you been open?" A.—"A month." Q.—"What are your sales running?" A.—"\$28 a day." Q.—"What are you doing to get people in?" A.—"I have a fine window display." Q.—"Are you not doing anything else?" A.—"No." He assumed that because he put in a fine window display and opened the door the public were going to make a mad rush into the store and buy his product. The window display was fine. The fans in the window were all moving, and so had an interest value, but no pulling value. There was nothing about price, nothing about the fact that now is the time to take the fan while the weather is hot. There is all the difference in the world between interest and attention and pulling value to a window, and so it is with selling what you are advertising. You can run a whole page of advertising, and if you don't know how to write your ad. you won't get any replies. You won't pull. Advertising is a business. Very few contractors can write ads. We need a higher degree of intelligence in our advertising. Our merchandising methods have been bad and unmodern. If a man is going to run an electric shop he may be ever so efficient an electrical engineer or contractor, but he should go out and hire a man who understands merchandising. I would prefer that such a man did not know anything about kilowatts or voltages. He could be taught all he needs to know in a very short time; but you could not transform an engineer into a merchant in five years. It is a profession in itself. You know all about machines, and can tell when they are overloaded, and so on, but that does not make you a merchant. If you have not a merchandising man now, train one in your organization; send him to school and have him find out something about it.

5.—Recognition of the service functions of the contractor-dealer and recommends a differential when this service is performed.

That, of course, lies at the door of the manufacturer. We talk in terms of discount. Again I want to say that a little knowledge is dangerous knowledge. There are very few engineers who know anything about discount, just as there are very few commercial men who know very much about engineering. I only spent four years studying engineering, and I admit I do not know anything about it. It does not appeal to me at all. I will accept the superior knowledge of the engineer on an engineering problem, but I demand that he submit to my superior knowledge on the commercial side because I have over twenty-five years on the commercial end, and I can talk to him about the commercial end of the industry. Engineers talk about discounts. A

discount is one thing; compensation for services rendered is something else. There is no basis you can set up (and I will debate this point with any man in the country) whereby a central station under any condition should get jobbing compensation. They do not render jobbing service, and should not get it. Discounts should be given to anyone or everyone in or out of the trade, and they should be based solely on the cost of handling the product. In other words, a socket is worth so much on the manufacturer's shelf and worth so much in a case or carload. What can it matter to the manufacturer as to who buys the commodity so long as he gets the same price? That is a discount. Now we get into the trade. We have jobbers and contractor-dealers and central stations selling merchandise, rendering a service to the industry—selling advertising, displaying, warehousing, financing, accounting, taking care of depreciation and everything that comes with the passing of the product from the manufacturer to the consumer. Jobbers, contractor-dealers and central station rendering that service are performing a part of the industry's service and should receive compensation therefor. It is altogether different from a discount. It is just as different from a discount as kilowatts are from volts. You would not have to sit up all night to tell the technical man the difference between a volt and a watt or a volt and an ampere, but the technical man does not understand the commercial side of it, the difference between discount and compensation. We must have houses wired. We must have retail stores, and compensation for services rendered. Do not confuse the two propositions, and try to tear down, by getting some price that the dealer or jobber or central station is getting in the distribution of merchandise in the form of services rendered, by going to the manufacturer and telling him you want the discount the other fellow gets; that you want compensation for services you do not render. You are powerful enough to do it and you might force the manufacturer temporarily to give it, but it is not right and is not ethical. The jobber should get compensation when he renders a jobbing service, because that is a part of the internal problem of distribution. There is just as wide a difference between compensation and discount as there is between a volt and an ampere.

6. The sale of high-grade electrical material; the establishment of high-class specialty retail shops; improved specifications in wiring installations; and the introduction of liberal use of convenience receptacles.

The tendency of the electrical people has been to cheapen the product. You are faced with that situation right throughout Canada today. You have an influx of Japanese-made material the quality of which is disgraceful. If they want to come in and compete let them live up to a high standard. We all know the quality we are selling is bad enough, even the best we can get, with all the complications of voltages and frequencies and everything else. The public have become generally suspicious of what we are selling today. Let us not make worse the quality of the product; let us better it. Any contractor-dealer, jobber or central station that encourages manufacturers, and particularly foreign manufacturers, to come into this land, and will swallow the low price product, is a menace to the community.

7.—Broader education of the public concerning the problem of the electrical industry, and concerning electricity, its use and the application of household devices.

8.—Retailers applying intensive sales methods in connection with small devices used in home, factory, office, etc. (such as washing machines, vacuum cleaners, dishwashers, electric ranges, electric heaters, household heating devices, sewing machine motors, fans, lamps, portables, fixtures, vibrators, hair dryers, ice machines, etc.).

Let us take the public into our confidence and tell them

the simple story of the electrical industry. The Sunday morning papers are just filled with stories about fine touring trips, and how to change an automobile tire and put on a patch. We are being fed that stuff, and we love it, we just eat it up! But think of taking up a paper and reading all these things about the electrical industry! Why, that would let the public in on our secrets! The automobile fellow is telling Mrs. Goodwin how to fix a spark-plug, how to change a tire, and two thousand and one hundred remedies for preventing punctures—just a lot of idle talk which gets people interested in the automobile. Right now the average woman knows more about an automobile than most of us do.

We should have public lectures illustrated by lantern slides and moving pictures. Once a month a man should be delegated to lecture to the public in every community in the country. People will flock to these lectures and will subsequently flock to the industry and have their houses wired and purchase appliances, because they will understand what they are about. We must tell them; it is our job to educate them. We get the trade papers and advertise to each other—just go around in circles all the time. We have a lot of manufacturers downstairs telling the fellows in the trade what fine things they have, and that is a good idea; but the real idea is to go out and tell the public about it. We want to advertise in the trade to keep the trade alive to what is going on. We want more public exhibits, and when we have these exhibits we don't want some fellow with a great big static machine taking 200,000 volts through him and scaring the people to death. That is the kind of stuff we put in the electrical shows. We do not want to deceive the public at all—there is enough deception to the business without deliberately practising it!

9.—The introduction and application of proper cost-accounting methods in wholesale and retail merchandising, particularly if either function is a minor department of a company.

That is clearly understood. The idea of that is to make each department of a business self-sustaining. Departmentalize your business. Put in proper cost-accounting methods and make each department carry itself. After you effect that you will have real economy. Some of the central stations take great pride in that! Again, a little knowledge is dangerous knowledge. If it is good accounting to divide your business into departments and get the cost of departments, why not divide the departments into commodities and get the cost of commodities? Don't tax the selling of rubber-covered wire on to the washing machines.

10.—Free and unobstructed flow of trade along most economic channels, without attempt to direct it through fixed channels.

That comes, of course, through the medium of the closed association, where jobbers and contractors, and sometimes even central station men combine for the purpose of forcing manufacturers to submit to uneconomic policies. It is not sound, and will not last. Trade must take its natural flow. I am sorry Mr. Chase did not read a paper he showed me while we were coming up on the train, entitled "The Channels of Distribution in the Electrical Industry." After you have heard it you will be convinced that the industry is travelling at the present time in unmarked channels. We fail to mark the channel with proper beacons, and trade differentials and compensation, but we force it through arbitrary channels and make it just as difficult as we can to get our product from the producer to the consumer.

11.—That central stations conduct retail departments for the sale of lamps, appliances, devices, portables, etc., and operate same in accordance with the ethics of retailing and with full regard to proper cost accounting.

12.—That all interests conduct retail depart-

ments to be operated at a profit. The adoption of this policy on the part of central stations and jobbers will result in a large number of concerns entering the retail field.

That brings us back to proper cost-accounting. It means that the fact that you are in the central station or in the retail business is no reason why you should operate that business at a loss, and tax it on to somebody else's kilowatt.

13.—Recognition of the service function of jobbers in the distribution of supplies and recommends a differential when full service is performed, and a proportionate differential is performed, and a proportionate differential when only a partial service is rendered.

I have already explained the difference between compensation for services rendered in the trade and discount, and we are commencing to grasp that.

14.—Jobbers determining, through proper cost accounting, the cost of warehousing, and selling their principal commodities, to the end that each principal commodity will carry its proper portion of overhead.

I have just told you where the jobbers have appropriated money to determine these costs.

15.—Open meetings of all trade associations, including meetings of executive committees.

I am very happy to say that principle has been adopted practically all over the country, and we have made wonderful progress through the result of this open meeting idea.

16.—That the electrical press become an integral part of each division by honorary or associate membership, and that unrestricted publicity be given the proceedings of all meetings.

That has taken place. Publicity is what you want. Leave it to the good judgment of an editor of a technical paper to publish what will help the industry.

17.—The formation of a national lecture bureau, with state and local staffs. The function of the staff would be to carry on educational work within the industry and before public gatherings. Service to be gratuitous.

18.—Recognition of the principle that any action be taken by a single division which affects another division is seldom satisfactory unless each division affected is represented.

That is simple. If the central station, the manufacturer, jobber or contractor-dealer are about to take action which affects another group, representatives of that group should be called in, because in these days you cannot, simply because you have the power, decide what is good for the other fellow, and force him to submit to it. He will not do it. If you are going to take action that affects another group, call in the representative of that group and talk things over.

19.—The appointment of committees by the National Electric Light Association, Electrical Supply Jobbers' Association, Association of Electrical Contractors and Dealers, and various manufacturers' associations to meet together to study the problems of the industry and to co-operate in finding their solution.

20.—Consolidating or reconstructing overlapping organizations. A committee comprising representatives from each association should be formed to study this question and submit a plan.

21.—Eventually a single organization in the electrical industry, consisting of national, division, state and local sections; also main national sections for the solution only of functional problems of the several branches or groups.

I expressed to your president my hope that before long these problems will be indexed and catalogued and studied and answered. When that has been done co-operation will be effective and our organizations will be developed in every community, province and state, until there is a single organization in the States and a single organization in Canada,

and eventually a single international organization with proper sections and groups to represent every section of the country. Then we will get the best ideas together and the industry will progress.

Mr. Goodwin concluded by referring to his Wheatstone bridge chart and explaining the parallels between the operation of this instrument and relationship of the various elements in the electrical industry.

DISCUSSION

Mr. Perry: Mr. Goodwin said that on the Pacific Coast the amount of electrical energy sold per capita per annum had been increased from \$5 to \$30. That, with an average of five people per family would amount to \$150 per family per annum, or \$12.50 per month. That is so much in excess of the average domestic monthly bill of the Hydro System that I am interested in getting an average of the kilowatt hours sold per month.

Mr. Goodwin: The per capita consumption of energy, and the industry's products, appliances, and so on, amounted to \$30; that is, the total of appliances and energy. The energy consumed, of course, has gone up proportionately with the general increase. The average rate on the Pacific Coast I am not in a position to give you definitely off-hand, but I would say that the residential rate amounts to about seven cents, and the average commercial rate amounts to about three cents. Success on the coast is due not to the low rate of energy, but to the intensive selling methods the organization has employed in the industry in that section. The California campaign is a matter of print, and I shall be glad to furnish you with a copy to show how they work on a co-operative plan in that section.

It is not due to any low rate for current, but to intensive selling and advertising and publicity and the popularizing of the industry's product that the success mentioned has been achieved.

Window vs. Newspaper Advertising

Mr. Hicks (Oshawa): I would like to ask Mr. Goodwin with regard to advertising, whether he considers window display better than newspaper advertising. I refer, of course, to a proper, up-to-date window display, with life in it as well as appliances.

Secondly, I would like to ask him about the feature of the central station managers and superintendents having all the useful appliances in their own homes. Appliances such as the range, the washing-machine, the toaster, the vacuum cleaner, and so on. I think it would be a good idea to take a census of the number of managers and superintendents present here today who are using such appliances.

I would also like to know whether the hardware stores have become factors in retailing electrical appliances, and as to what methods Mr. Goodwin would suggest to stimulate the sales of household appliances.

Mr. Goodwin: Window display and advertising should go jointly in any campaign. The biggest asset a dealer has is a good location and a good window display, because the window display is the most inexpensive means of advertising he can employ. It is the most direct means. The department store has set the best example in that respect. They employ professional window dressers, and if there is anything delights the hearts of the ladies of the land it is to stroll up and down the streets and look into the windows of the great department stores. The dealer has the window at his command, and that is the best means he has of attracting the public to his store. If he can afford to supplement it with newspaper advertising, it is desirable that he should do so.

In the past the dealer has been handicapped by the fact that he had no knowledge of window-dressing, and even if

he had, he was not supplied with the proper facilities to dress his window. The manufacturer, generally speaking, has been deficient in not supplying proper window-dressing materials, but within the last couple of years the manufacturers have given a great deal of thought to that side of the question and are today spending enormous sums of money to equip the dealer—and when I use the term “dealer” I include the central station also selling appliances—with proper facilities for window-dressing and display. I know two or three manufacturers who are right now working on uniform window displays with interchangeable cards that will be supplied to the dealers or the central stations with stores, by means of which the window can be readily changed.

We must make it easier for the contractor-dealer to dress his windows. Some of the manufacturers in the States have employed professional window dressers, and they are sending them around to dress the windows of the dealer and the central station, with the idea that the dealer and central station will delegate a man to accept this training and do the window dressing himself. Window dressing is a business. It is a mistake to put a lot of dumb animals in a window and expect the public to walk up and show a lot of enthusiasm. I would say to the ordinary dealer that the window display is the biggest asset he has.

The Hardware Store

With reference to the hardware store, it has simply filled a popular demand. The electrical man has not properly gone after the business, and the hardware man is simply filling the demand. He will always be a medium of distribution, and will also sell a percentage of electrical material and his business will increase, but the total sales by him will decrease as we employ more intensive methods. The very nature of our product will call the public to the specialists' shop if the goods are presented in such a way that they will appeal to the public, and we can render a special kind of service that the hardware or department store cannot render. The business will flow through our channels, but the hardware store will always be a factor. He will always pick up a lot of the drifting trade that comes along and his business will increase. If he sold 15 per cent. of the product in the past he will perhaps sell 5 per cent. in the future, but that 5 per cent. will represent a 200 per cent. or 300 per cent. increase over his present volume of business. There is nothing to fear in the competition of the department and hardware stores. They will vend the cheaper lines of product than we, and will employ bargain sale methods. They will parasite our industry as far as we permit them to do so. They will lose a dollar in the sale of the flat-iron in order to soak the consumer with \$3 or \$4 extra on a white goods sale, but I do not believe that any reputable manufacturer in the electrical industry will tolerate his product being distributed through that type of merchant.

In the United States we are permitted to select our own customers, and I do not believe the manufacturer will select the bargain sale type of merchant as the means of distribution. The electrical people should sell the high-grade product, and if they do so they will acquire a reputation in the minds of the public that will secure their patronage.

Standard of Wiring

About what is being done to improve the standard of wiring: I think organization is causing the contractors to appreciate their responsibility to the industry, and has done more to elevate the standard of wiring than any other thing. Recently in New York we arranged meetings between the Institute of Electrical Engineers and the American Institute of Architects, and we are now drawing up standard specifications of various types of jobs, and by elevating the standard of the specifications put out by the architect and the

engineer better work will be produced by the contractor. You could drive a horse and wagon through most of the specifications you find now. Then the fact that a lot of contractors have been writing their own specifications for architects and engineers has been a bad business. It has precipitated dishonorable methods among the contractors. The contractor who writes a specification thinks he is in an advantageous position, and puts a lot of jokers in the contract, and the other contractor knows it.

We must have the specifications written by engineers who make it their business to write specifications, and then we will have a great improvement along that line. With the development of the contractor into a merchant with a store to back up his contracting business he will be less dependent on contracting, and there will be a tendency to do time and material work rather than contracting work, and as soon as you get the contracting dealer to say “I would not like to take a contract for wiring your house, but I will do a real good job for you on a percentage basis,” he will make more profit on a good job than on a poor job. The tendency seems to be to drift away from taking the job on a contract price except in the case of large installations where a good character of work is generally performed.

Receptacles and Plugs

With regard to standardizing receptacles, in the United States the question is being dealt with by five or six of the manufacturers. They had agreed on a standard, but these various devices were patented and each fellow thought his device was the best. I suppose you have the same jealousies in Canada. I think, however, that the combined strength of the electrical industry should be enough to make these fellows standardize. Put them in a room and lock the door and deprive them of water and food and say “You don't come out until you standardize!” If you cannot get them together in that way let each and every man in the electrical industry concentrate himself on one article, and then the majority of them would be obliged to give in. It is selfishness on the part of the manufacturer that is holding the whole industry back. We should be ashamed of ourselves to sell a woman a flat-iron for \$5, \$6 or \$7, with a cord and plug, a toaster with another cord and plug, and still another device with another cord and plug, and so on. I have 40 devices with a cord and plug for each one, and not one interchangeable. Why should we have to buy a cord and plug every time we buy another device? It is a fool proposition, and we are not getting anything out of it. We not only want the means of connecting them in, but also the devices themselves standardized as to terminals, so that every device using a certain wattage up to 500 or 1,000 watts will have one kind of plug, and every other device above that some other kind of plug. I would like to see this organization pass a resolution and then go and talk in real, understandable language to the manufacturer who will not agree to standardization.

Mr. Phelps (Sarnia): Have the Contractors' Association in Ontario men they can send out into the country to give the contractor-dealers information? In the city of Sarnia we have four or five contractor-dealers whom I have been trying to get together to accomplish something, for some time past, without success. My object is to enable them to give the public a better service in our city, but they all seem to be jealous of one another.

Mr. McIntyre (Toronto): We have neither the funds nor the time to make a regular business of educational work. At the same time, if Mr. Phelps of Sarnia will send a request to our Association, I will either come up myself or get somebody to go up. Within the past week I have held

meetings with the contractors in Hamilton and Kitchener, and am now in communication with Ottawa.

Contractors' Specifications

Mr. Goodwin mentioned specifications by contractors. There are a great many advantages in that. As you probably know, we have been forced to do it by the almost absolute ignorance on the part of the best engineers of matters pertaining to interior wiring. I do not think any of you will disagree with me on that, because very few engineers in Canada today have experience of inside wiring, and our Association officially stated our position at a meeting last winter of the Toronto section of the American Institute of Electrical Engineers. We said we would be only too glad when there were enough engineers to standardize, to bring high-class work to industrial and domestic installations.

I would like to ask Mr. Goodwin a question which has been put in my mind by several outside of Toronto contractors: Granting that the proper policy for central stations is to specialize and to emphasize campaigns to exploit and develop new devices, does it necessarily follow that the central station, whether publicly or privately owned, should have to go into the retail business to attain that end?

In Toronto we have the Toronto Electric Light Company and the Hydro-electric System both carrying on great stores. As far as I know, neither of these systems is cutting prices. But there is hardly a decent electrical shop in Toronto of the kind Mr. Goodwin sets up as the ideal. There is not one to my knowledge. Going out of town to the various municipalities in Ontario where the local system has no electric shop the contractor-dealers have shops 500 per cent. better than those in Toronto. So I ask the question: Is it better for the central station or the contractor-dealer to open a retail store?

Advertise the Specialty

Mr. Goodwin: If I were running a central station and had an appliance department, I would concentrate my advertising on the specialty article, I would not waste five cents advertising a flat-iron. I would concentrate my efforts on the new goods that came out, such as an ice machine, or a dish-washing machine or an electrically operated sewing machine—something new.

The thing is to get the public to buy from some place. There are a certain number of people in the community who prefer to deal with the independent merchant and others who prefer to deal with the Hydro. If the central station is going to run a campaign, why not have a family campaign? Why not all get into it? If we are going to put on a campaign in connection with washing machines, why not everybody get into it?

In Albany they were selling about five dish-washing machines per week to the whole community. A campaign was put on, and everyone of the dealers was permitted to display washing machines in the central station display room, and to send their demonstrators there to demonstrate them. They put a colored girl in the window with an old washing tub and right alongside of her a modern electric washing machine, and they sold 250 machines in two weeks!

Then there arises the question of instalments. All these higher priced devices must be sold on the instalment basis, and it is the simplest thing in the world to provide a means of financing instalment sales. Many of the small dealers cannot carry the instalment business, but you cannot sell washing machines for cash in any quantity, and the same remarks apply to vacuum cleaners, dish-washing machines or sewing machines. The small dealer cannot finance the instalment sales, and in the absence of his ability to do so the utility, the manufacturer or the jobber should do the financing. If they are unable to finance then they should

go collectively to the bank and work out a co-operative plan of financing.

Financing Instalment Plan

In the United States we have provided through our modern system of banking a means of financing instalment sales. I have a copy of the whole plan here and would be very glad to leave it with you if you are interested. In the city of Chicago very recently the groups have come together, and the Commonwealth Edison Company have offered to finance the instalment plan. I believe co-operation will produce a better result. I believe business will be set back if the utility goes out of the appliance business. I think they should concentrate their efforts on the new devices. The old devices, such as the iron and the toaster, will automatically sell themselves. I have learned from sad experience that in the communities where the highest degree of co-operation is developed and the central station has gone out of the retail business the contractor-dealer got right back into the rut. The contractor-dealer needs some sort of stimulation to keep him inspired to greater effort.

Mr. McIntyre: I did not intend to suggest that in Toronto the systems should go out of the retail business. What I intended to ask was whether in the case of communities which were already being well served by the well-run local shops in co-operation with the local system, should the local system there go into the business? I will ask this additional question: If that system did have it under consideration, would it not be best to consult the local contractor-dealers before taking any such step?

Mr. Goodwin: I would say that would evidence a spirit of co-operation, but I would have to be shown the community in which any contractor-dealer was properly cultivating all the business, and developing an intensive market. There is no such thing as saturation. They have not yet reached saturation in the case of the old foot-power sewing machine. We cannot think of saturation. I would say that if I were running a central station even where the contractor-dealers were rendering good service, I would go into the appliance business and would co-operate in such a way with the contractor-dealer that we would be better friends every day. I do not think the contractor-dealer is enough of a merchant to appreciate the importance of this job, nor has he the financial ability or experience to carry the job along, and I believe if the central station goes in and co-operates, the business will increase.

Compensation for Services Rendered

Mr. Merrick: I would like to ask Mr. Goodwin to draw a distinction, if he can, in regard to compensation in connection with jobbers and central stations. I do not know whether Mr. Goodwin is aware of our situation here, but I would like to ask him if that remark refers to the Hydro utility store or municipal store. The Hydro Power Commission of Ontario at the conclusion of last January's Convention (the last time we had the pleasure of hearing Mr. Goodwin speak, and the substance of which speech we feel we have absorbed and made every effort possible to put into effect all throughout the system) carried out every detail of the work that was possible. In that connection we have incurred considerable expense. We have got the manufacturers, the energetic manufacturers, to come out and co-operate with us in the great work of revolutionizing the question of sales in Ontario, and where it has been necessary to open a new store we have invited the local representative of the manufacturer to join us. Such work we feel is worthy of some compensation. Therefore, I ask Mr. Goodwin is not some compensation due to the Hydro Power Commission

in the capacity of an exploiter and in jobbing or re-selling a commodity?

Mr. Goodwin: I would say yes. You have raised a question which is fundamental, and if not properly handled will lead to a very serious situation. I take it that at least some of the manufacturers are not granting to the Hydro what you consider fair compensation for the services you render. Now, it all depends upon the approach you make to that particular manufacturer. We must be absolutely fair and broad-minded in this whole proposition. There exists to every electrical manufacturer in Canada a real menace in the Hydro if you exercise to the extreme your power to purchase. What I mean is this: If I were an electrical manufacturer in Canada I would hesitate to put myself in the position of marketing my commodities through the Hydro because of the tendency to make me dependent on you as my sole outlet. In other words, if the Hydro system develops along the line that each of these respective communities purchase their own requirements and their own particular style and designs independent of any other plant I think the manufacturer will willingly and gladly give you proper compensation for services rendered, but if the tendency on the part of the Hydro system is to develop concentrative buying through a central force and uses its purchasing power to squeeze the manufacturer down to minimum prices for his product and compels him to use the Hydro as an outlet, I would fight you. Let us take the question of meters. Supposing someone gets up in a meeting like this and says we should go to one manufacturer and give him all our meter business based on the total consumption of all these various plants. You would say that is a good idea, and we will do it. That, however, means that one manufacturer is going to get the business. Let us carry the idea to the extreme. Let us bring all the plants in Canada together and apply the same principle, apply the combined purchasing of all the plants to a single meter. You have one manufacturer of meters and you are going to drive everybody else out of the business. Temporarily it is a fine thing for you, but God help you when that manufacturer drives everybody else out of business!

Concentrated Buying a Menace

Let us take another situation: I do not know how many meter manufacturers you have in Canada. Combine your purchasing power and concentrate on one manufacturer. In Ontario your demand is unusual, and the manufacturer must provide facilities in order to take care of this one very desirable purchaser (very desirable while the going is good), but at the end of the year somebody in this room gets a grouch and says "I prefer the Westinghouse. I like the aluminum cases," and so on and say "We will divide this up and give it next year to the Westinghouse or the Canadian General Electric," then what is the fellow who has put a lot of money into this meter business going to do? He has a factory and a lot of men and a lot of capital tied up, and he will close the whole plant out, and the other fellow is going to build a new factory and steal the men that the other manufacturer trained up. What would you do? The manufacturer would be a fool who would put money into that scheme with the uncertainty that is bound to come through concentrated purchasing power. You must never get the manufacturer in the position where you become a menace, because he is going to fight you.

A Voice: What about concentrated selling power?

Mr. Goodwin: Just as bad as concentrated manufacturing if you put it on your product. The greatest development will come with the greatest diversity of manufacturing institutions. The greatest development in the electrical business will come with the great diversity of manufacturers, but if you put all your manufacturing into the hands of one man he will become lazy. I can sense what the manufacturers

in Canada and the United States fear. I think it is bad to concentrate the manufacturing to one single unit, so that you are dependent on a single company. I think it is bad for a manufacturer to be dependent on a single purchaser. There is a real menace to you as well as to the manufacturer, to the people of Canada as well as the men in the industry if you concentrate your purchasing power. I think it would be a very unwise thing for the Hydro Commission to attempt to constitute itself a distributing medium if that is your scheme.

Mr. Merrick: I think that applies equally to every manufacturer in the electrical industry. I further take it that the question of compensation regarding the utility store or the Hydro Power Commission as a whole is one directly for the Hydro Power Commission to deal with. In that connection I will ask who is going to further the idea of a "Goodwin plan" in the province of Ontario where we as energetic electrical men are desirous of having it applied if not the Hydro? Mr. McIntyre made remarks a moment ago about not having a man permanently employed to go out and organize the contractor-dealers. May I state that we have in many cases assisted you, and I think I can find sufficient support in the room to confirm that Mr. Phelps offered his services to organize the contractor-dealers.

If I am wrong in interpreting the Goodwin plan at this late date I would be very glad to have it explained now, because we are very desirous of working along ethical lines rather than antagonistic lines. It is a new plan and we are open for education. If we are wrong we want to be set right.

Mr. Goodwin: I do not understand that you have a wrong interpretation, and I do not know that I have said anything that differs from what I have said before.

Manufacturer on Defensive

In answer to your question about compensation for services rendered, I say you should get that. I attempted to picture what I thought was the reason why you had not received it. That is a question that perhaps has nothing to do with my plan. It is a question of an individual manufacturer trying to preserve himself, and I can see why a manufacturer would hesitate to give compensation to the Hydro or anybody else if he thought that compensation meant his own destruction.

The Goodwin plan does not contemplate the idea that any man is going to submit to a proposition that means his own destruction. At the same time I attempted to point out what I thought would be a menace to your business if you attempted any such methods of concentrated purchasing. Let us assume that the Hydro elected to go into the jobbing business. There is nothing in my plan that would prevent them doing so, but they would not and could not go in and develop an equal kind of competition with other jobbers. The other jobbers would have to go out and sell their wares on the basis of services rendered. They would have to present real good selling arguments in order to convince you or a contractor-dealer to buy his wares. But if the Hydro went into concentrated purchasing for the purpose of obtaining a low price it would result in the contractor-dealer sitting back and acquiring the habit of laziness. We lose sight of the fact that the success of a business is not made by the price we purchase a commodity at. There is no money made in the purchase of anything, and you men in the operation of your plants will not make money by purchasing in quantities at low prices. You make money when you sell an article, whether it be real estate or merchandise or electrical energy. The way you purchase very often determines the type of market you are going to sell. A week ago you could buy stocks and bonds at one hundred and forty, and two days ago at one hundred and twenty, but who wants to buy

stocks or bonds on a declining market because they are cheap? Every business properly run works on the law of percentage, a certain percentage for overhead is added to the commodity, and the percentage of profit made on a dollar is more than the profit on eighty cents so long as you can sell satisfactorily to the public. There will be no success in your Hydro development in your concentrated purchasing power. The little you might save through enjoying a quantity discount will not help you, because I have attempted to point out that the big job is to sell the idea to the public, and price does not enter into it. The Hydro wants security, but the healthy development of Canada demands that you give security to the electrical manufacturers, too, because if you kill them off and become dependent on the United States and England for your product you will see the manufacturers in those countries soak it into you.

Mr. Merrick: Compensation for services rendered, as I understand it in regard to jobbers, is a standardized principle among manufacturers. This exploitation work which Mr. Goodwin mentioned in January last is very expensive in regard to ice machines, dish-washing machines, and other little-known appliances. I would like to ask Mr. Goodwin to make a statement as to the distinction he would draw between allowing compensation to the Hydro for services rendered and anybody else?

Mr. Goodwin: I have said I cannot see any distinction between allowing compensation to the Hydro and anybody else for services rendered. There is no argument there at all. It is absolutely sound, sensible business. The only reason that would prevent it is the one I attempted to point out, where a manufacturer sees ahead of him a menace. Self-preservation is still the first law of human nature, and compensation disappears when a menace appears. You would have to be more specific and cite the manufacturer and the particular commodity, and the rate of compensation.

Proper Compensation

Let us take a specific case in the United States: Some of the contractors say that the compensation allowed by the manufacture on the sale of motors is insufficient to cover the cost of handling and selling them, and the manufacturers say the cost is excessive. I say to the contractor: "You make a contention. Where are your costs?" The contractor says "I do not know, but my judgment dictates that I am losing money on the sale of motors." In other words, he knows nothing about it.

The motor business in the United States amounts to possibly \$35,000,000 a year and the contractors ask \$3,500,000, 10 per cent. I would ask anybody for that myself. I would not be a fool in asking for it, but you would be a fool in giving it to me.

The manufacturer on the other hand says the compensation is sufficient, and I say to him "Let me see your figures to prove it is sufficient," and the manufacturer does not know, and there we are with locked horns. We have to get statistics to prove the case.

A man in Cleveland named Oppenheim was interviewed and said "You are preaching compensation. Before you do so, why don't you tell the General Electric to give us decent compensation so that we can live? I said "I don't know why the General Electric do not give you decent compensation, but as I recall your sign over your door it reads: 'Oppenheim, the price-cutter,' and you are the worst price-cutter in Cleveland, and I take it the manufacturer has been giving you too much compensation." We get back to the proposition: What is the right basis of compensation? The best way to measure it is to feed it to the dealer, jobber and Hydro in small doses, and immediately he starts to cut the price withhold it. You in Canada are the worst lot of price-cutters I ever saw. You must be getting too much compensation or

you would not be giving it away. You are getting compensation from the manufacturer for rendering a service, and instead of keeping it as your profit you give it away. The answer must be that the manufacturers are giving you too much. The compensation should never be any more than a man will keep. Perhaps the Hydro have given it away, I don't know. If you will tell me the specific case I will endeavor to give you a better answer, but while we are talking in generalities that is the best I can say.

Mr. Shearer (of Smith Falls): I think the conditions suggested by Mr. Goodwin and the remedy therefore lies with the individual local sales manager. He is not compelled to buy from the Hydro Power Commission, and if they suggested we stock up with one line of goods the province over, I think we would be very foolish, because I think the most of us will agree that where we have a varied stock we will in a good many cases make a sale that would have been lost if we had only one line of the same article. I mean if we were stocked up with only one manufacturer's irons and no other irons there would be a good many cases where we would not sell an iron because we did not carry a cheaper line. It lies with each individual sales manager to stipulate the stock he will carry, and in that way we can vary the stock.

Protection for Dealer

I would like to ask Mr. Goodwin in regard to the instalment plan how he would protect either the jobber or the central station against being fleeced by spurious customers in the case of house-wiring. Where there is an appliance we can protect ourselves through a lien, but I do not think we would stand much of a chance of attempting to remove the

The product we have to sell cannot be sold for cash in any great quantities.—W. L. Goodwin.

wiring from a house if it was not entirely paid for and the party left the country or refused to complete the payments. It seems to me the house-wiring proposition should be a cash one.

Mr. Goodwin: Of the choice between the selling of appliances on instalments and house-wiring on instalments so far as security is concerned, I will take the house-wiring. We know from experience of over 20 years in every line of endeavor that the credit losses on instalment sales are less than 1 per cent. As a matter of fact, they average one quarter of one per cent. in the case of all the big instalment houses throughout the United States. You are selling to what might be regarded as the most unreliable kind of purchaser, the one that has to buy on the instalment plan, but there is something about the people of this continent that makes them keep their instalment payments as faithfully as they will keep their religion. If you give a man a washing-machine on sixty days' credit he will beat you right and left, but if you sell it on the instalment plan you won't have to chase him all over the country. In the case of house-wiring, however, he cannot move it away and it becomes a lien on the building all the time.

The President: Before we adjourn there is a resolution to be discussed in regard to the Standardization of Plugs and Receptacles.

The following motion was carried unanimously:—Moved by Mr. R. H. Martindale, seconded by Mr. J. E. B. Phelps:

That this Association urge that all reasonable steps be taken to introduce into this country a standard plug and receptacle for all appliances, and that the Standards Committee take active steps in this important matter.

Electricity Helps the Farmer

The Matthews Engineering Company have issued an attractive new booklet on farm lighting and power plants from which the accompanying illustration is taken. Any man, if he was once a boy on the farm, will understand this young gentleman's appreciation of the work of the little electric motor. This is the plant handled in Canada by the Northern Electric Company.

One of the most complete farm installations that has come to our attention is that of J. W. Cameron, who lives near Readlyn. Mr. Cameron's buildings are all of first-class construction, and are electrically lighted throughout. Over

Think about it for a moment.

the door of his garage is a lamp which lights the walk from house to barn, and is controlled from four points. Thus there is no need of a lantern, as the light can be turned on at the house, and extinguished on reaching the barn. In the barn is a $7\frac{1}{2}$ h. p. motor driving a Bowser feed mill. Experience has shown just where to set the slide gate in the feed-chute so that the mill gets just enough underground oats and corn, and so it runs without attention. Nearby is a 1 h.p. motor belted to a shaft formerly driven by a windmill. This shaft runs outdoors to a pump which delivers to a concrete tank from which pipes run to various watering troughs. One of these troughs which serves the beef animals, is placed in the wall of a shed so that it can be reached from without or within. Formerly there was trouble with this freezing, but Mr. Cameron has put in a little electric immersion heater, taking 500 watts, which effectively keeps the water ready to drink. Since there are about 150 head of cattle the saving of this device is obvious. The motor-driven feed cutter, too, means no hauling of feed over heavy roads, and no shortage of ground feed at any time.

Electricity lightens household tasks too, and Mr. Cameron isn't one of these men who keep all the conveniences for himself. His house is well lighted throughout, and has a complete plumbing installation, supplied by a small rotary pump driven by a $\frac{1}{8}$ h.p. motor. This pump delivers into a 3 ft by 6 ft. pressure tank. In the laundry is a combined washing machine and wringer driven by a $\frac{1}{4}$ h. p. motor. In summer Mrs. Cameron's kitchen is always cool for she uses an electric range. This has three burners on top and an oven underneath. In winter, too, there is no fear of fuel shortage, and no delay should the range fire go out. Other household

equipment is an electric flat iron, a sewing-machine motor, and an electric vacuum cleaner. In the garage is a motor-driven grinder which keeps tools sharp:

Mr. Cameron has a farm of 320 acres, on which he usually feeds 150 head of cattle and 300 hogs. His electricity bill totals \$8.00 to \$10.00 per month. Current is purchased from a nearby central station which operates a 2300 volt distributing system. As is customary in this community, each user pays for his share of whatever line connects with the nearest distributing line. He also pays for his transformer, a $7\frac{1}{2}$ kw., and protective devices. The central station installs the meters. The rate for current decreases with the amount used, thus making it easy for the farmer to run several motor driven devices. His equipment is all Westinghouse. By their aid it is possible for Mr. Cameron with the help of one boy, to take care of his stock during the winter alone and in the summer to concentrate his time on really productive work.

The strike of electrical wiremen in Montreal continues, the principal contractors declining to accede to the demands of the union for 75c an hour. The officials of the latter asserted that the Administrative Commissioners had decided to substitute in city contracts the union scale and conditions for the fair wage schedule previously adopted, but the commissioners explained that this was only temporary in order that urgent work be done, and that the city would be willing in the future to pay a scale agreed upon by employers and the men. A deputation of the Electrical Contractors Association of Montreal, (affiliated with the Association of Montreal Building & Construction Industries), consisting of R. Moncel, H. Vincent, F. J. Parsons, W. Shaw, E. J. Gunn and Fred Smith, with Mr. D. K. Trotter, secretary, saw Mr. E. R. Decary, chairman of the Commissioners, and protested against the city paying rates beyond those current at the time contracts were given out, and also against the alleged decision to employ none but union men. Mr. Decary explained the reason for the temporary payment of 75c an hour, and declared that no arrangement had been made whereby only union men would be employed.

It is reported that dealers, having exhausted their supply of electric fans due to the abnormally hot weather during June, are hesitating to replenish their stock lest the temperature takes a drop. It might be well to remember, however, that we are just at the beginning of our ordinary summer and, in all probability, have practically two months of "fan" weather ahead of us. The contractor-dealer has more than a sporting chance to make a big turnover on this line yet.

"Our Army & Navy" of Washington, D. C., edited by Captain J. Walter Mitchell, devoted a page and a half in its December issue to an "appreciation" of Mr. Louis Steinberger, president and general manager Electrose Manufacturing Company, Brooklyn, N.Y. Mr. Steinberger is evidently one of those rare characters who doesn't tell his left hand what his right is doing—particularly when it's making large and frequent subscriptions for patriotic purposes. The electrical world has long known Mr. Steinberger as an inventor of note. They will be no less pleased to know him in the other capacity.

PHILLIPS' ARMOURED CABLES

Branches : Toronto, Winnipeg, Regina, Calgary, Vancouver

Current News and Notes

Creston, B. C.

The East Kootenay Light and Power Company propose extending their lines to serve Creston, B. C., and the surrounding district.

Drummondville, Que.

The new plant of the Southern Canada Power Co., at Drummondville, P.Q., is now in operation. The present capacity is 7000 h.p., and the ultimate capacity 18,000 h.p. The equipment includes two 3,150 kv.a. 60 cycle 2,300 v. a.c. generators, direct connected to vertical turbines, under a 32-ft. head. The transformers are 1000 kv.a., oil insulated and water cooled.

Fredericton, N. B.

Improvements and extensions to the amount of approximately \$175,000 are announced for the current year by the New Brunswick Telephone Company. New copper circuits for the North Shore section are included in the estimates.

Kitchener, Ont.

The Waterloo-Wellington Railway, operating between Kitchener and Bridgeport, has been offered to the city of Kitchener at a price not yet stated.

Montreal, Que.

The Duncan Electrical Co., Ltd. of Montreal, announce that they have made arrangements with Mr. L. A. Cochrane, of Winnipeg, late of the Northern Electric Co., Ltd., to assist in the furtherance of sales for Duncan Products throughout Western Canada. Mr. Cyril B. Clarke, of Geo. Clarke & Son, Halifax, will perform the same duties for the Duncan Electrical Co., Ltd., in the Maritime Provinces.

The Modern Electric Machine & Equipment Company, Montreal, have registered.

The fares of the Montreal Tramways Co. will have to be again revised—doubtless in an upward direction—owing to the increase of \$1,300,000 in wages now being paid to the employees. The Tramways Commission are now studying the data for the new schedule.

The Sewing Machine & Electric Supply Company, Limited, Montreal, have registered.

The city of Outremont, P.Q., propose to spend \$13,000 on electric light extensions; \$7,500 on underground conduits; \$15,000 on burying cables, and \$5,000 on poles, etc.

The Safety Electric Company, Montreal, have registered.

Ottawa, Ont.

The General Electric Supply Company, Ottawa, Ont., have closed their branch store.

Owen Sound, Ont.

A new electric store has been opened in Owen Sound, Ont., by E. B. and F. J. Potts, who have just returned from overseas. The firm name will be "The Sound Electric Company." They will carry on a general contractor-dealer business.

Pembroke, Ont.

The town of Pembroke, Ont., will, in co-operation with the Pembroke Electric Light Company, remove all the present wires and poles from the main streets and install modern "white-way" standards. Additional improvements to the lighting system will be made in other sections of the town.

Parry Sound, Ont.

The town of Parry Sound, Ont., has let contracts for the installation of a hydro-electric plant which will contain two units. These will be approximately 650 and 1050 h.p. turbines driving 425 and 750 kv.a. generators respectively. Power will be obtained from the Seguin River and the work

of erecting the dam is already under way by the W. M. Fletcher Company, 55 Bloor Street West, Toronto. The generators are being supplied by the Canadian Westinghouse Company. C. H. & P. H. Mitchell are consulting engineers.

Regina, Sask.

A general advance in rates on the government telephone system in Saskatchewan will be made on September 1st.

Sydney, N. S.

A committee from the town of North Waterford, N. S., recently waited on the officials of the Cape Breton Electric Company asking that the railway be extended to that town.

Toronto, Ont.

The Nitro Electric Company, Toronto, is named among recent registrations.

A deputation from the Belleville city council and board of trade recently waited on Premier Hearst asking assistance in the development of iron mining in the northern part of Hastings county. It was pointed out that the government could help by securing cheaper power. The present rate is \$17 per h.p. The premier promised an investigation.

The Automatic Electrical Display Company, Toronto, have registered.

The Electric Works Company, Toronto, have registered.

The Ontario Fixture and Electrical Company, Toronto, have registered.

Vernon, B. C.

A meeting was recently held at Vernon, B. C., to discuss a proposed hydro-electric power development at Shuswap Falls on the Adams River to serve the entire district from Kelowna to Kamloops. Among the benefits would be the electrification of the Kamloops-Kelowna branch of the C. N. R., cheap power for industrial purposes and electric lighting, as well as for irrigation pumping. The matter will be discussed further at a municipal convention to be held at some central point.

Windsor, Ont.

A by-law designed to grant the Sandwich, Windsor and Amherstburg Railway Company a straight five cent fare was defeated by a large majority.

Winnipeg, Man.

A newspaper report states that the Winnipeg River Power Company, backed by Mackenzie and Mann interests of Toronto and allied closely with the Winnipeg Electric Railway Company, has started work on a large power plant at DuBonnet Falls on the Winnipeg River, 75 miles north-west of Winnipeg. The ultimate capacity, it is stated, will be six units of 28,000 h.p. each, or 168,000 h.p., and the project which will be completed in three years, will cost \$7,000,000.

Personals

Ald. E. W. Sayer, of the Sayer Electric Co., Montreal has been re-elected trustee of the City of Outremont Protestant Schools by the ratepayers of the city.

Mr. V. Laursen, of the B. C. Electric Company, Vancouver, was recently in Oakland, Cal., attending the tenth annual convention of the Pacific Coast Claim Agents' Association.

Major T. E. Ryder, D.S.O., M.C., has been appointed general manager of the Rudel-Belnap Machinery Co. Ltd., Montreal. Major Ryder recently returned in command of the 7th Canadian Siege Battery after four years overseas service.

Lighting Fixtures—Catalog issued by Trans-Com. Lighting Products Corporation, New York, illustrating and describing special lighting fixtures for public buildings and residences; electrical conduit fittings and boxes and marine electrical appliances.

Ten-Cent Fares for Bay State System

The public trustees of the Eastern Massachusetts Street Railway, Boston, Mass., voted to withdraw on July 1 the 7-cent tickets and tokens from the Bay State system. It was announced that on and after that date the initial fare north and south of Boston would be 10 cents, as it has been since Jan. 8 for a single cash fare. The 7-cent tickets and tokens will be redeemed at 7 cents each.

The public trustees took possession of the property on June 1. An estimate of the earnings and expenses for the month

indicates a deficit of approximately \$300,000. Nothing was earned toward interest charges or the principal of the State guaranteed bonds.

Steps have been taken by the public trustees substantially to reduce the management expenses throughout the system. Notwithstanding these economies, neither an 8-cent nor a 9-cent fare would produce enough revenue to meet the cost of service, as provided by law, or even the interest charges, which must be met if the company is to remain solvent.

As soon as the cost of service can be determined accurately in each of the 12 districts under the home rule plan of operation and accounting, which also goes into effect July 1, the fares in these districts will be changed accordingly.

It is the intention of the public trustees to issue at frequent intervals statements showing the receipts and expenses of each district.—Electric Railway Journal.

With No Spark Brushes

Friction on the
Commutator is Reduced
to a Minimum

NO SPARK BRUSHES don't crumble, crack or break. In hundreds of cases they have outlasted 8 to 12 sets of ordinary brushes. Grades and sizes to suit all Electrical Machines. Let us prove our claims to you. Our engineers are at your service to insure proper selection of grade best suited for each machine.

Our interesting bulletins explain all about these brushes. Write for them.

"ANTI-SULPHURIC" ENAMEL

In many manufacturing plants such as engraving houses, electro-plating factories, etc., acid fumes are present to such a degree as to be decidedly destructive to exposed surfaces. For all such conditions "Anti-Sulphuric" Enamel will completely solve the problem and provide a quick drying flexible, glossy coating for the job. It is absolutely resistant to acid fumes and atmospheric influences. Use it in Accumulator rooms.

Electrical Books—Special Prices

The following Books are Offered Subject to Previous Sale:

- "American Electricians' Handbook, a reference book for practical electrical workers, by Terrell Croft. 712 pages, with over 900 illustrations. Published by McGraw-Hill Book Co. Price \$3.00.
- A Handbook on the Steam Engine, by Herman Haeder. Published in 1914 by Crosby, Lockwood & Son. 522 pages, illustrated. Price \$3.00.
- A Laboratory Manual of Alternating Currents, by John H. Morecroft, E.C. Published in 1912 by Renouf Publishing Company. 248 pages, illustrated. Price \$2.00.
- Baudot Printing Telegraph System, by H. W. Pendry. Published in 1913 by Whittaker & Company. 144 pages, illustrated. Price \$1.00.
- "Central Stations," by Terrell Croft, 1st edition published in 1917, by McGraw-Hill Book Co., Inc. 332 pages, illustrated. Price \$2.50.
- Direct-Acting Steam Pumps, by Frank F. Nickel. Published in 1915 by McGraw-Hill Book Company. 258 pages, illustrated. Price \$3.00.
- Direct Current Machinery, Theory and Operation of, by Cyril M. Jansky, B.S., B.A., 1st edition, just published by McGraw-Hill Co., Inc. 285 pages, illustrated. Price \$2.50.
- Dynamo-Electric Machinery, by Francis B. Crocker, E. M., Ph.D. Published in 1908 by American School of Correspondence. 236 pages, illustrated. Price \$1.00.
- Electric Arcs, by Clement D. Child, Ph.D. Published in 1913 by D. Van Nostrand Company. 194 pages, illustrated. Price \$2.00.
- Electric Car Maintenance, by Walter Jackson. Published in 1914 by McGraw-Hill Book Company. 274 pages, illustrated. Price \$2.00.
- Electric Railway, by A. Morris Buck, M. E. Published in 1915 by McGraw-Hill Book Company, Inc. 390 pages, illustrated. Price \$3.00.
- Electric Railway Engineering, by C. Francis Harding, E. E. Second Edition. Published in 1916 by McGraw-Hill Book Company. 416 pages, illustrated. Price \$3.00.
- "Electric Traction," a treatise on the application of electric power to tramways and railways, by A. T. Dover. Published in 1917 by Whittaker & Co. 661 pages with 518 illustrations and five folding plates. Price \$6.00.
- Electrical Injuries, by C. A. Lauffer, M.D., published in 1912 by John Wiley & Sons. 77 pages. Price 50 cents.
- Electro-Dynamics, by Charles Ashley Carus-Wilson. Published in 1898 by Longmans, Green & Company. 298 pages. Price 50c.
- Elements of The Infinitesimal Calculus, by G. H. Chandler, M.A., Prof. Applied Mathematics, McGill University, 318 pages, cloth bound. Published by John Wiley & Sons, 1907. Price \$1.40.
- Elementary Principles of Illumination and Artificial Lighting, by Arthur Blok, A.M.I.E.E. Published in 1914 by Scott, Greenwood & Son. 235 pages, illustrated. Price \$1.00.
- Elementary Graphic Statics, by John T. Wight. Published in 1913 by Whittaker & Company. 226 pages, illustrated. Price 75c.
- Elementary Magnetism and Electricity, by Cyril M. Jansky, B. S. Published in 1914 by McGraw-Hill Book Company. 212 pages, illustrated. Price \$1.50.
- Examples in Alternating-Currents, (Vol. 1), by F. E. Austin, B.S. Published in 1915. 223 pages, illustrated. Price \$2.00.
- Examples in Magnetism for Students of Physics and Engineering, by Prof. F. E. Austin, B. S. Published in 1916. Price \$1.00.
- First Aid in Case of Electrical Shock, by Dr. John Woodman. Published in 1908 by the New York Edison Company. Illustrated. Price 50 cents.
- "Fuel," by C. F. Herington, recently published by D. Van Nostrand Co. 211 pages, with 84 illustrations. Price \$3.00.
- Handbook of Machine Shop Electricity, by C. E. Clewell. Published in 1916 by McGraw-Hill Book Company. 461 pages, illustrated. Price \$3.00.
- How to Make High-Pressure Transformers, by Professor F. E. Austin. Second edition, just published. 48 pages, illustrated, price 65c.
- International Library of Technology, Vol. 11-B, on Electricity and Magnetism, Electrodynamics, Electrical Resistance and Capacity, The Magnetic Circuit, Electromagnetic Induction, Chemistry and Electro-Chemistry, Primary Batteries, Electrical Measurements, 585 pages, fully illustrated, half Morocco bound. Published by The International Textbook Co., 1905. Price \$3.50.
- International Library of Technology, Volume 14-C on Storage Batteries, Incandescent Lighting, Arc Lighting, Interior Wiring, Modern Electric Lighting Devices, Electric Signs, Electric Heating, 540 pages, fully illustrated, half Morocco bound. Published by The International Textbook Co., 1905. Price \$3.50.
- "Powdered Coal as a Fuel," by C. F. Herington, recently published by D. Van Nostrand Co. 211 pages with 84 illustrations. Price \$3.00.
- Practical Electric Illumination, by Terrell Croft, First edition, published by the McGraw-Hill Book Co. 225 pages, illustrated. Price \$2.00.
- Principles of Direct Current Machines, by Alexander S. Langsdorf, M. M. E. Published in 1915 by McGraw-Hill Book Company. 404 pages, illustrated. Price \$3.00.
- Principles of Alternating Current Machinery, by Ralph R. Lawrence. Published in 1916 by McGraw-Hill Book Company. 614 pages, illustrated. Price \$4.50.
- Principles of Electrical Design—D.C. and A.C. Generators, by Alfred Still. Published in 1916 by McGraw-Hill Book Co. 365 pages, illustrated. Price \$3.00.
- Radiodynamics—The Wireless Control of Torpedoes and Other Mechanisms, by B. F. Miessner. Published in 1916 by D. Van Nostrand Company. 206 pages, 112 illustrations. Price \$2.00.
- "Radio Communication, Theory and Methods, with an appendix on Transmission over Wires," by John Mills. First edition, just published by McGraw-Hill Book Co., Inc. 205 pages illustrated. Price \$1.75.
- Radiation, Light and Illumination, by Steinmetz. Published in 1909 by McGraw-Hill Book Company. 304 pages, illustrated. Price \$2.50.
- Standard Wiring, 1919 Edition, 25th Year. The National Authority on Wiring and Construction. By H. C. Cushing, Jr. Leather cover, pocket size. Price \$1.50 postpaid.
- Steam Power Plants—Their Design and Construction, by Henry C. Meyer. Published by McGraw-Hill Book Company in 1903. 158 pages, illustrated. Price 50c.
- Steam Turbines, by Robert M. Neilson. Published in 1903 by Longmans, Green & Company. 294 pages, illustrated. Price \$1.00.
- Steam Turbines, by Kennedy. Published in 1910 by Whittaker & Company. 100 pages, illustrated. Price \$1.00.
- Telegraph Practice, a Study of Comparative Method, by John Lee, M.A. Just published, by Longmans-Green & Co. 102 pages. Price \$1.00.
- Telegraphy—A Detailed Exposition of the Telegraph System of the British Post Office, by T. E. Herbert, A.M. Inst. E.E. Third edition. Published in 1916 by Whittaker & Company. 985 pages, 630 illustrations. Price \$2.00.
- Telegraphy, by Sir W. H. Preece, K.C.B., and Sir I. Sivewright, M.A. Published in 1905 by Longmans, Green & Company. 504 pages. Price \$1.00.
- Test Methods of Steam Power Plants—A Reference Book for the Use of Power Station Engineers, Superintendents and Chemists, by Edward H. Tenney, B.A. M.E. Published in 1915 by D. Van Nostrand Company. 224 pages, 85 illustrations. Price \$2.50.
- The B.I. Hand-Book, published by British Insulated & Helsby Cables, Limited. Second edition. 448 pages, illustrated. Price \$1.00.

- The Dynamo (2 volumes), by Hawkins & Wallis. Published in 1909 by Whittaker & Company. Price \$4.00.
- The Lighting Art, Its Practice and Possibilities, by M. Luckiesh. First edition, just published by McGraw-Hill Book Co., Inc. 229 pages, illustrated. Price \$2.50.
- "The New Competition," by Arthur Jerome Eddy, 6th revised edition, price \$1.60.
- The School of Practical Electricity (Electrician's Course in 2 volumes). Volume 1. Published by Electroforce Publishing Company, Milwaukee, Wis. 410 pages, illustrated. Price \$4.50.
- The Practical Railway Spiral, by L. C. Jordan, C.E. Published in 1913 by Van Nostrand Company. 155 pages. Price 75c.
- Transmission Line Crossings, by Frank F. Fowle. Published in 1909 by D. Van Nostrand Company. 69 pages, illustrated. Price \$1.00.
- Treatise on Thermodynamics, by Dr. Max Planck. Published in 1903. 272 pages. Price \$1.00.
- Wray's Manual of Car Lighting. Published in 1915 by Wray Publishing Company. 340 pages, illustrated. Price \$1.50.

UNIVERSAL BUSHINGS FOR FLEXIBLE TUBING

Neat, Secure and Accessible

Nos. 1 & 3

They grip the flexible tubing securely. Can be installed in a moment by simply slipping over the tubing. Fits "knock out" tightly. Permits easy removal of flexible tubing for inspection without dismantling switch box or injuring bushing or tubing.

Nos. 2 & 4

Universal Bushings

combine function of porcelain, bushing and tape, and give the job a finished mechanical appearance. Try them and be convinced.

Approved by the National Board of Fire Underwriters

"Pittsburgh" Show Window Reflectors

ARE A LIGHTING ECONOMY

They redirect the light to give the fullest illumination on the window trim, thereby eliminating waste distribution.

These reflectors promote lighting efficiency and economy. Their first cost is nominal, yet their saving in light is very considerable. Send for further information to-day.

Illustration shows "Pittsburgh" Reflector No. 100 for 100 or 150 Watt Lamp. Dimensions.—Height, 8 1/4 inches; Width, 8 3/4 inches. Holder, 2 1/4 in. Form "O".

ECONOMY renewable FUSES

are in greater demand than any other fuses because ever since their first appearance on the market their performance has proved them worthy of the trust placed upon them.

They are **accurately** rated—efficient in operation. They are **safe** in every respect—not sometimes but **always**.

As compared with the use of one-time fuses, they cut annual fuse maintenance costs 80%.

An inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

Economy Fuses and Links live up to their name. The economy they effect is considerable—too big for you to ignore. Besides, you will profit by the added measure of safety they insure.

Sold by all electrical jobbers and dealers.

Motors for Sale

Subject to prior sale, we are offering the following Motors for Sale

- 1—Packard Electric Co. Motor, 30 H.P., 3 phase, 60 cycle, 550 volt, 900 R.P.M., complete with pulley and starting box. Serial number 257.
- 1—Canadian Crocker-Wheeler Co. Motor, 10 H.P., 3 phase, 60 cycle, 220 volt, 900 R.P.M., size 116-Q, complete with pulley and starting box. Serial number 7309.
- 1—Wagner Electric Co. Motor, Type B. P., Model 14-V, 10 H.P., 3 phase, 60 cycles, 220 volts, 1720 R.P.M. Complete with pulley and starting box. Serial number 104529.
- 1—Canadian Westinghouse Motor, Type C.C.L., 2 H.P., 220 volts, 3 phase, 60 cycles, 1700 R.P.M., with pulley. Serial number 4254.
- 1—Packard Electric Co. Motor, 15 H.P., 3 phase, 60 cycles, 220 volts, 1200 R.P.M., complete with starting box and pulley. Serial number 640.

All of these Motors are in First Class Running Order.

WALGER CONNECTORS

Patented Canada 1917.
Patent Pending U. S.

Solderless Connection

Insulating Shell and Cap

No mistake can be made with the use of Walger Connectors. There is only one Walger way and that is the right one. No Blow Torch, no acid, tape, or solder, etc.—a screwdriver and a knife to strip the wire, that's all.

For Condulet Connections and Tap Joints

Passed by the National Board of Fire Underwriters and the Hydro Electric Power Commission for No. 12 wire and under.
Ask your jobber for them and Discard that Blow Torch.

Resurface Commutators While in Service

The Ideal Resurfacer will keep your commutators in perfect condition. You can forever eliminate the trouble and expense of shutting down equipment to turn down commutators on a lathe. They can be kept in perfect condition by the occasional use of the Ideal Resurfacer while running under full load.

IDEAL COMMUTATOR RESURFACER

is a manufactured abrasive block that will quickly cut down high mica ridges and high bars, smooth out grooves and low spots on your commutators. It is non-metallic and non-copper collecting. Not a natural stone, sometimes hard and sometimes soft, that clogs with copper dust, but a specially prepared product of uniform density and cutting quality throughout.

FOR "D-C" OR "A-C" EQUIPMENT

The Ideal is equally effective on both "D-C" and "A-C" equipment—it will keep commutators and collector rings smooth, free from sparking and save in wear and tear upon carbon brushes. It will pay for itself many times through increased efficiency of your equipment and in time and labor saved, keeping commutators and collector rings in A-1 condition.

SEND THE COUPON

In order that you may convince yourself of the value of the Ideal we want you to try it out on your own equipment. If you like it send us a check—if not return it at our expense—the trial will not have cost you a cent. That is fair—fill out the coupon now while the matter is in mind.

The Ideal Commutator Dresser Co.

ESTABLISHED 1849
BRADSTREET'S

Offices Throughout the Civilized
World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

THE BRADSTREET COMPANY

Offices in Canada: Halifax, N.S.; Hamilton,
Ont.; London, Ont.; Montreal, Que.; Ottawa,
Ont.; Quebec, Que.; St. John, N.B.; Toronto,
Ont.; Vancouver, B.C.; Victoria, B.C.; Win-
nipeg, Man.; Calgary, Alta.; Edmonton, Alta.;
Sydney, N.S.

THOS. IRVING,

Man. Western Canada, Toronto.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a Specialist in Repairs. Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an absolutely reliable job. You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine (Profit). Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the Trade Discount (More Profit).

Others are doing it. Why not you? Write about it.

Generation, Transmission and Application of Electricity

These Four Exclusive Points of Advantage

Form the Basis of the Tremendous Success of the

BUSS Renewable FUSE

Point 1

Terminals are seated in long metal grooves. Impossible for terminals to be out of line. Long seat prevents any possible strain on

fuse link. Seating of terminal makes unnecessary any indented or odd shaped washers that must be properly seated to assemble the fuse.

Point 2

Self-Aligning Element. No renewable fuse can be put together when the terminals and link are not assembled in a straight line, yet, the BUSS FUSE IS THE ONLY ONE IN WHICH ARRANGEMENTS HAVE BEEN PROVIDED TO ENABLE AND GUARANTEE THE ASSEMBLY OF THE ELEMENT IN A STRAIGHT LINE.

(Link sets between lugs on terminals. Link cannot be pulled out of line when bolts are pulled up tight).

Point 3

Metal Ring Inside of Tube. The metal ring for holding the cap and terminals is fastened INSIDE the tube. THIS MAKES THE BUSS FUSE THE ONLY ONE ON THE MARKET NOT AFFECTED BY THE SHRINKING OR SWELLING OF THE FIBRE.

(The more the fibre shrinks, the tighter the ring is held. Consequently, the fuse always remains tightly closed, preventing the escape of flame and gases).

Point 4

Floating Element. In assembling the terminals and link on a renewable fuse, a variation in length as much as $\frac{1}{8}$ " occurs. This is due to the clearance in the screw holes in the link and terminals. Due to shrinkage of fiber, variations in length of the case also occur. THE BUSS IS THE ONLY ONE IN WHICH MEANS ARE PROVIDED FOR AUTOMATICALLY COMPENSATING FOR THESE VARIATIONS.

(This is accomplished by making the slot in the terminal much wider than the thickness of the washer seated therein, thereby permitting a limited movement of the terminal).

Best Known Cable

Reel In Canada

THE demand for Northern Electric products and the fact that they are made by the largest manufacturers of bare and insulated wires and cables for electrical distribution is a positive assurance of quality.

They are as near perfection in both dependability and durability as experience, workmanship and superior materials, combined with the most modern machinery, can make them.

Bare copper, rubber covered and paper insulated, lead covered cables of Northern Electric manufacture—are designed by the most capable engineering skill and tested to ensure safety and efficiency to the fullest degree possible.

Our nearest House will be pleased to submit specifications and prices upon request.

THIS IRON and TOASTER "Coast to Coast" Consumer Campaign is for your benefit.

Thirty leading papers with a combined circulation of more than a million copies are now carrying the message of these Higher Grade Irons and Toasters into Canadian homes.

Here is your opportunity to get your share of the business which this National advertising will create.

You make a nice profit on each sale—the goods are made in Canada and cannot be matched for mechanical excellence, beautiful finish and quality of materials. No finer or more reliable Heating Appliances were ever placed on the Canadian Market.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Useful in the Shop and Laboratory for the Measurement of Resistance.
Adapted for Fault Locations in Telegraph and Telephone Lines and Cables.

The Type S Bridge is a thoroughly practical instrument for shop and field use. Being complete in every detail it is ready at all times for immediate use. It is easily portable, its weight being but 8 pounds. The precision of adjustment of its coils (Rheostat 1/10 per cent., Ratio 1/20 per cent.) insures accurate measurements. The galvanometer, the weakest element of such an instrument, is unusually rugged. It is a separate element and may be removed for examination or repair by taking out two screws. The battery is of the ordinary "flash light" type, and renewals may be procured practically everywhere. The price is \$66.25 net, f.o.b. Philadelphia, boxed for shipment.

Bulletin No. 530 describes this instrument.

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

A Time and Labor Saving Screw for Electrical Contractors

Robertson ^{Patented} Socket Head Wood Screw

In these days of high costs of labor and material, you want to save wherever you can. The Robertson Socket Head Wood Screws will save time, money and material. They are easy to drive—all you have to do is place the screw on the driver—it sticks there, enabling you to drive at arm's length if you wish. Indispensable for use in hard-to-get-at places, such as between joists, under floors or between narrow openings.

Let us prove our statements by sending a few samples and our prices.

We supply bits to suit any ratchet, also drivers in all suitable styles free with first order.

Strong Selling Features of Durable Daytons Mean Real Profit for Dealers

Illustrating Durable
Dayton No. 676

Six blade 12 or 16 inch
Oscillating Fan, con-
vertible to bracket
position.

Durable Dayton Fans are easy to sell and good to sell because of their quality—they mean satisfied customers and repeat orders—Dayton fans are sturdily made, for long, untroubled service. They consume less current and their square-end blades deliver more breeze.

The line is complete, including electric ceiling, desk, and wall bracket models for alternating and direct current, exhaust fans and water motors. Easily adaptable; all Dayton desk fans can be immediately converted into the wall bracket type.

Opportunity to "Cash In"

Demand is for quality now, stronger than ever before—Daytons have held the fan quality leadership for 26 years, the best fan for every purpose.

Durable Dayton dealers are given co-operation; sales helps and advertising that brings in customers and profits.

For Security

"Guardians of the Peace"

"FRANKLIN" Devices, installed in your plant, are guardians of your peace of mind. You will soon learn to depend upon them and to put equipment worries behind you.

The "FRANKLIN" Disconnecting Switch, equipped with the "FRANKLIN" Positive Lock, cannot be forced open by electrical expulsion strains. The closed bridge above the switch-blade, formed by the locking jaws, prevents. These jaws can swing open only in a direction opposite to that of the resultant electrical force. Yet, by the rotating action of the cams on the pulling against the lugs on the lock-posts, a single easy pull with any hook swings open the jaws and withdraws the blade.

Other well-known "FRANKLIN" products are Post-Type Insulators, Potheads, Doors for Bus and Switch Compartments, Instrument Cutout Switches, Cleat Type Insulators, Air Pressure Relays, etc., and the new "FRANKLIN" Fuse. Write for descriptive Bulletins.

To Help You Sell More

Benjamin Two-Way Plugs

The flat one-color reproduction shown here can nowhere near do justice to the original "Three-Plug Carton" which is handsomely printed in four colors, to show ten of the many handy uses of the Benjamin Two-Way Plug, and is an effective, constantly working salesman whether it be placed on the counter, in the show-case, on the shelf, or in the window.

This attractive carton not only catches attention, but suggests the need for more than one Benjamin Two-Way Plug in every home—and gives a real *cash* reason for buying three instead of one.

Place your order NOW—and get this carton working for you

"Turning One Socket into Two" is the title of a new illustrated folder in colors, which is available now for distribution.

Send us your name and address.

Benjamin Electric Mfg. Co., of Canada, Limited
Toronto - Ontario

The Sale Which Builds Permanent Good Will For Electrical Service

In the final analysis the success the electrical dealer and central station will meet in promoting the use of electrical home equipment is largely up to the service given by the devices they supply.

Cheap devices of questionable reliability may be easy to sell at the start, but every sale of an unreliable device becomes a boomerang which makes it increasingly difficult to get new converts to the electric way.

On the other hand, reliable devices—though the prices may make the first few sales a little more difficult—create an appreciation of electric service which grows of itself after it is given a start, just like the snowball rolling down hill. For every satisfied user of a reliable household

electric device lends her voice to the cause of the electrical dealer and central station.

When electrical dealers and central stations supply R & M Motor-equipped devices, they are sure of an operating reliability which will react favorably upon their future business.

The R & M Motor insures reliability from the power standpoint. And as a rule, the maker who selects these motors for his equipment is the kind who is building his equipment on a quality basis throughout.

And R & M Motors help make the initial sales too, for as a result of dominant advertising R & M Quality is known to everyone in a way which prejudices buyers favorably toward the R & M equipped machine.

Pulverized Coal Opens up Possibilities of Future Economies

In considering ways and means of cutting the cost of operating our various industries, one of the factors that is receiving more attention is the use of pulverized coal. Pulverized coal was used many years ago in the Portland cement industry where pulverizing machines—one of the difficult problems in the way of development—were finally brought to a high state of efficiency. It is now being utilized at the rate of about six million tons annually in this industry.

This form of fuel has been gradually taken up by engineers in other industries. For example, the steel industry uses about two million tons annually; the copper industry nearly as much; it is being applied to railway locomotives where the demand promises to be enormous and, finally, stationary power plants are experimenting and reporting economies over the old stoker system.

Powdered coal, as applied to these industrial phases, is something more than the dictionary definition implies. The coal must be pulverized to an impalpable powder—so that at least 95 per cent. will pass through a 100-mesh sieve, having 10,000 openings to the square inch. The finer the coal is pulverized the more efficiently it can be burned because of the more nearly perfect and instantaneous combustion. Pulverizing coal does not change the nature of the coal, though it does, in effect, change its form from solid to a semi-liquid. As the coal is pulverized it is mixed with air and when handled in a conveyor it flows like water.

Aside from greater efficiency, it is evident that the use of coal in this form would make possible the utilization of much of our supply at present useless. Low grades of lignites and mineral coals with high moisture content, waste coal around steel plants, silt waste at the mines and so on, will, with the development in powdered coal usage, take on a value equal to that of our best qualities at present. A further consideration is its applicability to transport through pipes. The day may yet dawn when our coal supply is available in our homes and factories at the turn of a tap, just as to-day we take water or gas.

Centralized Power Plants in England and Canada

An interesting item appears in the current issue of "Conservation" regarding the application of the same plan of centralization now being organized to take care of Great Britain's electric supply plants, to the western provinces of Canada, where somewhat similar conditions obtain. It is pointed out that the cost per kw. h. in certain sections of our prairie provinces, where demand is small and water power not available, runs anywhere from 15 to 19 cents. Against this sum it is figured that power from a centralized plant could be laid down at about 5½ cents over a radius of 150 miles.

There is doubtless enough force to this line of reasoning to justify a thorough study of the situation though, on its face, there surely can be no such discrepancy as that shown between the two figures quoted of 19 and 5½ cents per kw. h. The load factor of 40 per cent., which is quoted, is probably above the average that could be obtained, nor does the article state what allowance is made for depreciation, sinking fund, etc. If even a figure of 10 cents were possible, however, the expenditure would seem to be justified.

This idea of centralized plants, located advantageously to an easily available supply of coal, so that the question of transportation is one dealing with electricity rather than coal, is not new, of course, but has been the dream of many an engineer. Doubtless the biggest difficulty is the limited, intermittent and widely scattered demand for electric energy. Each year as the western towns grow—and they must grow again, though temporarily at a standstill—the dream will be nearer realization.

Then, too, there is the farmer to be reckoned with. Many a prosperous farmer has a demand equal to the village of former days. This prosperous element in our community, with its telephones, mail delivery, pleasure and utility automobiles, now see enough of town and city life to appreciate the advantages of electric power and light, and—some way or other—he is going to get them. Perhaps it will be in the form of individual plants, but the better way, without question, is the central plant. The farm demand may well be the means of changing our whole system of electrical supply.

Grand Du Bonnet Falls Development

Work has commenced on the new hydro development of the Winnipeg River Power Company at Grand du Bonnet Falls on the Winnipeg River, 14 miles north of Lac du Bonnet. At this point an island in the river forms a suitable location for the main dam, which will be about 2,000 feet long and 70 feet high, of concrete construction. The power house will be a steel and brick structure, 450 feet long by 140 feet wide and 100 feet in height. The design of the plant contemplates an installation of six units of 28,000 h.p. each, or an ultimate installation of 168,000 h.p. The initial installation will consist of two units; or approximately 56,000 h.p. A stor-

age reservoir of 2,000 acres, reaching upstream a distance of five miles, will be formed by the main dam. Power from the new plant will be transmitted to Winnipeg over a double circuit transmission line about 70 miles in length to a new transformer station to be built in Winnipeg. A second double circuit line will connect the new plant with the present line of the Winnipeg Electric Railway Co. from Pinawa to Winnipeg, about five miles south of the town of Lac du Bonnet. The company will thus have the advantage of a loop line to fall back on in case of breakdown. The Northern Construction Company, Limited, are general contractors for the work and will finance the cost until the bonds of the power company can be sold. The Winnipeg Electric Railway Company will be the principal user of power and any surplus will be used for commercial purposes. Mr. F. H. Martin, of Niagara Falls, is in charge of the design of the plant; Mr. R. S. Lea, of Montreal, is consulting hydraulic engineer; Mr. L. J. Herdt, of New York, has also been retained.

Water Powers of Pacific Province

The report on the water-powers of British Columbia, which is about to be published by the Commission of Conservation, places the total estimated 24-hour horse-power of the water-powers of that province at about 3,000,000 horse-power, in round figures.

This report completes the series of water-power reports which the Commission in 1910 undertook to publish. The investigation of the water-powers of British Columbia, of which the present report is the result, was commenced in 1911 by the engineers of the Commission, as stated in the report:

The report contains the following estimate of the water-powers of the province, which has been divided into districts, as follows:

	24-hour horsepower
1. Columbia river and tributaries (north of the International Boundary): This comprises the portion of the province lying between its eastern boundary and the watershed of the Fraser river . . .	610,000
2. Fraser river and tributaries: This includes practically the entire area of the great Interior plateau . . .	740,000
3. Vancouver Island . . .	270,000
4. Mainland Pacific coast and adjacent islands (except Vancouver islands): This includes all the rivers north of the Fraser, which drain into the Pacific . . .	630,000
5. Mackenzie river tributaries (a rough estimate made for inclusion in this summary) . . .	250,000
Grand Total . . .	2,500,000

The above total includes about 250,000 horse-power for plants already in operation, but they do not include about 400,000 horsepower, given in the tables in the report for power possibilities on streams like the Fraser, Thompson, Skeena, and Naas rivers, on which, because of the proximity of railways, or possible interference with the salmon industry, economical development cannot be considered under present conditions. Also there is still considerable territory, especially in the northerly portion of the province, which it has not been possible to investigate fully. These areas may yet disclose a considerable amount of power, as stated in the report.

In round figures, the report states, the total estimated 24-hour power, including an allowance for all the entities above mentioned, may be placed at about 3,000,000 horse-power.

The Armstrong, B.C., power and light station was destroyed by fire recently.

Super-Power Plants in Great Britain*

The recent decision to proceed with the super-power station scheme for electric supply in Great Britain calls to our notice what should be done along these lines on a more modest scale in certain portions of Canada.

The British plan to improve the supply of electricity throughout Britain contemplates the replacement of the numerous small stations now in operation, by fewer but much larger stations supplying extensive districts through high tension transmission networks. There will be a gain both in economy and fuel conservation and, in many cases, the quality of service will be much improved. This national electric supply operates under the supervision of five commissioners appointed by the Board of Trade; these, in turn, appoint district boards which include representatives of electric undertakings, of large consumers and of labour.

Lancashire is to be one of the first areas dealt with, the county being divided into three districts. Some of the smaller stations will probably be shut down immediately, the energy transmitted from larger existing stations being substituted. Following the building of the new super-power plants, the Commissioners will eliminate the remaining small stations and, also, the moderate-sized plants.

A similar situation, however, does not occur in Canada, as by far the larger portion of the capacity of our hydro-electric stations is to be found in what may be called "super-power" stations; many of them are also interconnected to allow more efficient operation.

There is, however a portion of Canada where the absence of water power makes it necessary to supply power from steam or other fuel agencies. This area, which comprises southern Saskatchewan and adjacent portions of Manitoba and Alberta, is becoming of much importance through its rapid agricultural expansion and its future needs should be anticipated so far as possible. As pointed out in a report on Electric Generation and Distribution in Canada, recently published by the Commission of Conservation, adequate supply of electric energy in this section is confined to a few large centres. The smaller municipalities have installed small electric plants, which are usually very expensive to operate and only give a night service. The high rates which have consequently to be charged and the limited service prevent the full benefit which should otherwise be enjoyed from the various uses of electric energy. All these small plants through concerted action could be replaced by a few large and more efficient ones, each supplying a fairly extensive district by means of electric transmission lines. The cost of production would be reduced to about one-third and a better service supplied.

The example given in the above-mentioned report illustrates the possibilities in the Estevan district. A central power plant at Estevan would supply transmission lines radiating in various directions covering a total length of 150 miles. The estimated demand, based on the requirements of the near future, shows a total of some 600 h.p. outside of Estevan. As the lines would only carry a light load they could be built cheaply with light conductors and at a cost possibly not exceeding \$2,500 per mile. If we allow a load factor of 40 per cent the cost of transmission would average 2½ cents per kw.h. The cost of production in the central plant would be from 2½ cents to 3 cents per kw.h., so that the electricity could be delivered for an average of from 5 cents to 5½ cents per kw.h. at the various small centres supplied. With a small plant, the present cost runs as high as from 15 cents to 19 cents per kw.h. Numerous other districts, if treated in the same way, would probably show advantageous results.

Routine Handling of Consumers' Accounts

Discussion on Valuable Paper by Mr. R. C. McCollum Which was Printed in Full in our July 1st Issue

Mr. Hillman (Toronto): Mr. McCollum is to be congratulated on his paper, which seems to me to cover the principal points of billing methods in an efficient way without going too greatly into details. I agree with Mr. McCollum in a good many of his statements. The day of the old-fashioned register, with 50 or more different consumers' accounts on the one page, is properly going into the discard. The continuous method of billing, which he advocates in municipalities of over 1,000 accounts, is proving by experience in the case of large concerns to be the most desired.

The point Mr. McCollum brings up in connection with the marking of the house numbers on the map is a good one, and I would elaborate that a little further by saying that houses on the street corners be definitely marked to show what the street number is. We had a case where the offices were over a store with separate entrance to both, but both bearing the same street number. We went to the proper officials in the City Hall, and he put a new number on one of the doors, and we have therefore had that building numbered to suit ourselves.

Mr. McCollum mentioned that various styles of billing forms are in use. Municipalities, in issuing bills, should always be very careful to see that the name of the municipality is on the bill. We frequently get cheques in our office with the bill attached to them, but on which no municipality's name appears. It was "Hydro," and the customer thought it must belong to us.

I want to commend the addressograph and any similar addressing system. One point Mr. McCollum might have mentioned in his paper is the fact that it serves as a check on seeing that every customer is billed. He mentioned a case where a customer might be billed or not, just as the man in the offices decided. But if an addressograph plate is made for every contract signed, that addressograph plate is used immediately to print the ledger card and the index card, and the plates are kept in separate files and the bills are handed to the addressograph clerk every day, and the cast-iron rule is made that every customer whose name is filed shall be billed.

I also agree very cordially with Mr. McCollum in his suggestion that, even though it may seem a little extra work, detailed records of cash receipts should be written up. We have a night staff that take the stubs from the teller, and the cash book is written up in accordance therewith. There is nothing so satisfying to the customer when he comes into the office as to be shown a detailed cash book and told "There is the amount of money you paid us" on a certain date. The fact that you have a definite chronological cash book enabling you to keep records in a business-like manner, will perhaps convince him he is mistaken.

I must confess I am not altogether in favor of a card ledger for very large offices. It is true that loose-leaf ledgers take up a good deal of room, but I do not see why our business is not just as important as the banking business, and it is only in the last few years that bankers would consider the loose-leaf ledger at all. They have been gradually converted to it. The card system is very easy as a matter of reference, but also very easily lost.

In his foreword Mr. McCollum has stated that the card ledger should be accessible to any number of clerks at the same time. Well, if your office staff numbers half a dozen

and they all go to the card ledger together there is no reason why a card should not be lost. I am frankly in favor of loose-leaf ledgers kept in a locked binder, although we do use card ledgers in some of our subsidiary bookkeeping, as, for instance, where there are not very many accounts to be handled, and they are thus easily replaceable.

I do not altogether agree with Mr. McCollum when he (as I would put it) deprecates the necessity of a trial balance being taken from the ledger cards. We have over 100 ledgers and about 52,000 accounts, and we take a trial balance off these ledgers every month. The end of the month charges do not go into those ledgers until about the 7th or 8th of the next month, because we include the bills for the meters read on the last day of the month in that month's working. In the case of the meters read on the 31st May, it is not possible to get them out before the 5th or 6th June; so that means that ledger is not posted until the 5th or 6th June. Every one of those ledgers was balanced by the 20th June, and we carry a general controlling account in the general ledger, and subsidiary controlling accounts for each of these ledgers, so when the ledger keeper takes off a trial balance he knows right away which ledger is out of balance. I do not think a public accountant would be justified in certifying to the customers' balance in which the balances were not verified by a detailed trial balance. He should have an opportunity of seeing whether they are bad debts or recent bills. If banks require trial balances for their ledgers I do not see why we should not require the same. You can do too much checking, but at the same time a certain amount of checking should be done to see that the accounts are right. If you are going to balance up the operation ledger, the construction ledger and the appliance ledger, I do not see why you should not take out a trial balance for the customers' ledger. However, Mr. McCollum has touched upon all the main points and has certainly presented to us a really up-to-date method of handling Consumers' Accounts.

The President: Mr. Hillman, has your ledger a separate sheet for each account?

Mr. Hillman: A separate sheet for each address.

The President: In other words, it is a card system bound in a book?

Mr. Hillman: Yes.

Mr. McHenry (Walkerville): There are one or two points in connection with the various features of this system which I thought might be of interest to various utilities. One is in connection with the use of the addressograph. We have been using the addressograph in Walkerville, and up to the end of last year we found it fairly satisfactory, but we were having new plates made in Toronto and found it impossible to keep the addressograph plates in accordance with the ledger cards. I might say that our population is rather a shifting one. People are always moving from one house to the other or away to Windsor or Detroit, and consequently we have a large number of changes to make in the addressograph, and we found it paid us to buy a companion machine to the addressograph, known as the graphotype machine, and make our own plates, and I think in any utility where the population is moving rapidly and changes are continuously being made it would pay that utility to do the same thing, to make their own plates. In that way plates can be made for new customers or changes

can be made the day following the application being taken in, and in that way the addressograph plates will always agree with the ledger cards.

Mr. McCollum has mentioned in connection with bills being sent through the mail, that window envelopes can be used. A few months ago I ran into something that may not have been brought to the attention of other municipalities. We use the color system for the different classes of accounts: white for residential, pink for commercial, and yellow for power, and we were using a white window envelope without transparency. The postmaster very kindly called my attention to the regulation which states that the envelope must be the same color as the bill. That is if you are using a yellow bill you must have a yellow envelope, and also the fact that no color shall be used for any bill which makes it difficult to read the address put on either by hand or by addressograph. For instance, some colors of ribbon might give you on a blue colored bill a very faint impression or an impression rather difficult to read, and the post office in accordance with the regulations can refuse to accept any such bill. I do not know whether any of the other utilities have had this brought to their attention, but we happen to have a postmaster who, I think, spends all his nights looking up all the little by-paths in the postal regulations and seeing they are enforced.

In connection with the use of the adding machine for cash book entries, I think that it could be used by utilities very successfully. It has been used by the Walkerville commission for a year and a half, and has proved very successful. Previous to the use of the adding machine for the listing of the accounts in the cash book the cashier's full time was occupied in taking in the cash and making entries in the cash book. After the installation of the cashbook system where the addressograph was used, we found that the cashier had from two to three hours a day to spare to devote to other classes of work, and in that way we were able to get considerably more work out of that particular employee.

Mr. Hillman made the point that he is not altogether in favor of the card ledger system on account of the fact that there is a liability of cards being lost. Of course, I am not familiar with what would happen in a large system, where they have something like 52,000 accounts, and there is a possibility of cards being misplaced from time to time, but we have approximately 2,300 account cards (we are using the card ledger system) and I may say that in the last year and a half, to my knowledge, there has never been one card misplaced or lost. We make it an absolute rule that only the billing clerk or the cashier himself may take cards out of the file; any other employee must leave the cards in the file, because they can be seen and any information necessary taken from them without removing them from the file; in that way the possibility of losing ledger cards is, to a large extent, avoided.

Mr. Childs: (Hamilton) After all, it seems to me that in rendering the accounts there are only two points that must be considered—service and cost. With the system outlined by Mr. McCollum services can no doubt be given, but cost also enters into the question. He suggests giving the meter reader three-quarters of the work he got. Of course, you are losing 25 per cent. efficiency there, and I question very much whether it is advisable to lose that 25 per cent.

There is one other question in connection with that system: He says it allows for unlimited expansion. Personally, I cannot see how that works out. If you divide the city into 25 districts and you are extending almost entirely east as we are, how are you going to allow for the expansion. We are extending to-day at the rate of about 2,000 consumers a year, and we must allow for that, but that will be overcome in a short time.

It is interesting also to learn that these cards were recommended for use five years ago, in view of the fact that we have been using them for the past seven years in the same colours suggested.

Mr. Hillman also mentioned the question of losing a card. We have, as I said, been using the card system for the past seven years, and we also have a meter reading card, and if the billing card is lost it is immediately discovered by the fact that the meter card is there and no place to post the meter record to. We have now over 18,000 consumers and have lost one card.

Instead of the cash book we have a duplicate account. We don't use a stub. We have a duplicate account made out with carbon paper on the typewriter and instead of the cash book we have those duplicates bound; they are our cash book.

Mr. Hillman points to the fact that it is very nice to show a customer an entry in a book and say: "You paid so much on such and such a day. We can actually show a duplicate or the accounts on that date and say: "There is the account you paid on that date." We have a double check on everything that goes through our office. Of course, we can put through four, five or any number of checks necessary, but I think it is generally considered good practice to have a double check.

The two things to be borne in mind are service and cost. Service is first, but there must be a reasonable limit or otherwise you could say: "Why not ten checks to see that everything is absolutely correct?"; and we don't use the cash book.

I think Mr. McHenry is mistaken in regard to the post office regulation. As I read it, it is that that portion of the enclosure must be white or of a light color. We have been using white bills for residences, blue for commercial, and yellow for power.

A. E. Clark (Central Ontario System): In connection with Mr. McCollum's paper I would say we are using the very latest form of loose-leaf ledger. A town of 2,500 customers will not have more than 100 pages in a ledger. I do not think we would consider that very cumbersome, especially as loose-leaf ledgers may be made to contain any number of pages and may have any number of binders you wish.

I would like to call attention to some of the statements made in the order in which he mentions them for the purpose of showing in what way the ledger fulfils the conditions which he lays down as being fundamental.

(1) "The record should be concise, but in sufficient detail that any error in the monthly bill can be promptly detected, or any complaint of a customer can be intelligently discussed without going back to the meter card or any other record."

The register is very concise in that it does not show any information which is not absolutely essential, but at the same time we are of the opinion that it shows all essential information, both from the viewpoint of the local office, the engineer, the bookkeeper and the auditor; the rate of consumption is shown; practically the only thing which does not appear in the register which appears in the cards is the meter reading, and personally I do not think that that is necessary in consumers' accounts, seeing that you have it in a meter reading card and do not in very many circumstances have to turn it up.

In conversation with local managers I have found that not more than 2 per cent. of our accounts have to be discussed in any one month with a customer, and therefore it should not be necessary to do a certain class of work for 98 per cent. of your customers which is not going to be of use.

(2) It should occupy the minimum office space and in its operation be as noiseless as possible."

I do not think that such a ledger as I have described occupies any more space than a card ledger, and it is very easily handled.

(3) It should be accessible to any number of clerks at the same time."

I do not think that the card ledger is inferior to the consumers' ledger in large offices, but I think in offices which have 3,000 or less, the register is more economical, because it takes less time to handle it, and by being subdivided into different books it is accessible in offices of such size to all the clerks who are likely to use it. In most cases it can be handled by one clerk or two at the utmost.

(4) The index should be rapid and definite and should provide for unlimited expansion."

Since the consumers' ledger is written over every year or two, it seems to me that question is not perhaps so important, because lines can be left for vacant and unwired houses, and street numbers can be skipped in localities where building is apt to be carried on in the near future. In a great many of the smaller towns there are no street numbers and therefore the register gives a perfect index, and subject indexes, either alphabetical or such as are mentioned in Mr. McCollum's paper, can be used equally well in connection with the register.

(5) It is especially desirable that when used in Hydro offices where a uniform system of rates is in force throughout the Province, the forms should be uniform, to secure the greatest measure of economy in installation and renewals."

In regard to the cost of forms, I do not think there is very much difference. In the case of the loose-leaf ledger the binder will last for some time, and all you need to do is supply new sheets. In our registers we have a narrow sheet for the names and a wider sheet for the financial information, various columns being provided for the different kinds of revenue. Since we started operating we have had practically no trouble in keeping the ledgers in balance.

(6) It should be possible to examine the charges for any particular class of service without disturbing the balance of the accounts."

If there is more than one ledger it should be quite possible with the consumers' ledger as with the cards, and they have the advantage of everything being in front of the reader, who just runs his eye down the page to get all the information he wants. Supposing a town had 2,000 customers, and the manager wanted to scrutinize the accounts to get an idea of how they were being handled? Those 2,000 could be handled in the one ledger, which could easily be looked over in one hour, whereas I would think it would take nearly a whole day to look over 2,000 cards.

(7) The records should be so kept that representatives of the Hydro-Electric Power Commission can, in the minimum time, extract from them such information as is necessary from time to time, to check the actual working out of rates and modifications of same as is required by the provisions of the Power Commission Act."

I think it is also necessary to consider that the accounts should be kept by the ledger-keeper in a manner which will keep the cost within a reasonable limit. We do not have to re-write the ledgers every year. There is a separate sheet for the names, but as soon as that sheet gets full or there are many changes in it on account of customers changing their addresses, that one sheet has to be re-written. However, at the end of two years should the register require to be re-written, by the use of the addressograph the whole of the names and addresses can be put in in one day or two days at the least. I tried this out myself in the case of one or two sheets, and I am convinced that by using the addressograph the annual re-writing of the ledger will no longer be looked forward to with any apprehension.

I think Mr. McCollum made a good point about the billing system. The recommendation which was made con-

tained several points which made it seem that the customer's money is received ten days approximately after the bill is sent out, and in the case of the Central Ontario system that would amount to nearly \$1,000 a year in interest.

In the case of those towns which have been using the continuous billing system there is no desire to go back to the old system. The Commission is putting addressographs in those offices where there are enough customers to make it worth while, and we find it nearly as expensive a proposition as the first, but the advantages are very marked. The metal plates provided are very easily changed, and if the customer moves you simply move the name from one location to the other. We have in a town of 2,300 customers found that the total cost of installation would not exceed \$300. Under the old system it took three days to address the bills, whereas it can now be done in a couple of hours; so you will see the machine soon pays for itself.

Mr. McCollum did not mention the practice of billing the residential and smaller commercial customers every second month instead of once a month. We find it will be a great saving, and in some cases extra work would have been necessary if we had not done this: in other cases the work was not properly done. We do not expect to have any difficulty with this, and the local managers are enthusiastic about it. I would commend this to the consideration of the municipalities, and to any others who have not adopted it. By dividing the town into sections and billing the sections alternately the work is almost cut in two, and the bills under Hydro rates are so small now that the customer will not feel any hardship in paying two months' at one time.

Mr. McCollum did not mention the use of post cards in billing these accounts. We purpose putting them into force in January, 1920, and we believe they will be a great saving in a considerable number of ways. The post cards are the regular stamped ones provided by the Government. There is a certain saving of office space and of time in enclosing the bill in this way. Money has been saved under this scheme amounting to \$100 for bills and \$675 for envelopes. The only disadvantage we see in the postcards is the possibility of defacement in transit. The other recommendation was to leave out the meter reading data.

I trust what I have said may appeal to some and lead them to believe that the register has some good points as well as the cards. I am convinced that in the small offices it is the most economical way of handling the accounts. I also think it is a good thing to show on the records the total amounts of the bills to the customers.

Mr. Yates: St. Catharines is one of the typical towns, about the same size as a large number of the larger towns and smaller cities on the system, and our smallest system is typical of that in use. We have two or three variations from Mr. McCollum's recommendations and I am glad to say that we can vary from Mr. McCollum's practice without getting into difficulty. We do not number our consumers' record cards in accordance with Mr. McCollum's system, that is, with a number for the street and a number for the district. We have the city divided into five districts, and one man who reads the meters. He used to be our general utility man, as some of you remember, but we have rather outgrown that now, and we find he is either getting lazy or we are getting too much business for him to do. We still continue to deliver our bills, and one man will read all our meters and take care of our bills at the same time, and if he gets behind we pick up a school boy to go out and make a few deliveries for him.

There is one thing that has not been touched upon, and that is the cash register in the cashier's office. We do not have to total up all our slips. It is a very easy thing to balance in the evening. We have our slips there, and our total on the cash register, and they are divided according to their

different classes or sub-titles such as "domestic light," "power" etc., so that at the end of the day it is simply a matter of taking off the main totals and the sub-totals and checking the cash with them. In the morning the cashier takes the slips from the day before and puts them in the cash book, and they have to agree with the different totals under the different headings of the day before. Then they are checked with the slips from the cash register and written off on the consumer's ledger card, and in that way you get a check there. Everything in our office is checked as it is so well and ably done in Hamilton, but I believe our costs are much lower than in Hamilton. Our last report shows that very conclusively. This register, I believe, is quite an advantage in relieving the cashier's office of work; also in being able to check back slips with the cash a great many mistakes can be avoided or rectified.

We hope to put in an addressograph in the near future. We have one clerk who makes all our bills, but we thought that with the addressograph it would lessen the amount of work as we expand.

One very good point in the paper is the idea of putting the name and address on the main bill, and the consumers' record number on the stub so that it only takes one im-

pression of the cash register, instead of two to give you the address and numbered bill.

Mr. Ferguson: (Peterboro) I was very much interested in the paper read by Mr. McCollum. As far as the card system is concerned, I might state that I have been using the card system for over 18 years, and when Mr. McCollum came along and mooted the idea of putting a card system in the office I was naturally very much delighted.

The first impression one receives is that these cards will get lost or stolen. During the whole of the 18 years I have been using the card system not one card has been lost. We had to give up the card system for two or three years, and we were introduced to the large ledger system—the largest ledgers I ever saw! The only trouble we had was to get them written up. Of course, on account of having used the cards before, we were very much against the using of the ledgers, but we had to do as we were told. We have been recommended to look at the banks and see the ledgers they keep. I do not know they are of very much use. Quite a number of bankers have found their way down to Kingston. Any system is open to fraud, but every convenience is found in the card system after you have become accustomed to its working.

Aluminium—The Electrical Metal

To both France and America belongs the credit for evolving the only practical means for producing aluminium and in both countries the production has been continually increased. The aluminium is reduced from an ore which is known as bauxite from the little town of Baux in the French Pyrenees where it was first worked. The first thing which occurs to us in connection with the reduction of an ore is simply "Smelt it." Why introduce this costly and troublesome electrical process? Well, that is just what the early experimenters thought about it. Now when an ore is smelted the oxygen combined with the metal has to be separated. This can only be done by introducing some other agent with which the oxygen can readily combine. In many instances a typical reducing agent is carbon in the shape of coal or coke. Iron ore, for instance, is loaded into a blast furnace with coal and coke and the result yields metallic iron and carbon dioxide. Now what happens if we load up a furnace with aluminium ore and attempt to do the same thing? Simply this that the aluminium will be no sooner reduced from the oxide than it forms a compound with the carbon and we are worse off than we were before. The fact is that aluminium is so ready to combine with other elements that it cannot be isolated in this way at all.

It would be tedious to go into the chemistry of the matter in detail but the only practical means found for reducing aluminium was to use an electrolytic process in which the metal would not tend to combine with the carbon of the electrodes. At the same time the temperature of the bath must be around 900 deg. C so that the electric current has not only to deposit the aluminium from the electrolyte to the bottom of the tank but has also to keep the whole mixture in a molten condition.

In actual practice the operations are more detailed than this. For one thing the ore has to be refined before it is available for the electrolytic furnace and there are different means of effecting this. In general, however, the process followed at the present day is substantially that of Heroult

and Hall. Water power is, of course, essential to the production of electrical energy in such large and continuous quantities as are used in aluminium production and some of the greatest water powers in Europe and America are employed in supplying an aluminium reduction load. It may, therefore, be called an electrical metal not only with regard to its uses but to its production.

8,000 Fold Increase in Production

While speaking of production it is interesting to compare the output of aluminium at the present time with that of only thirty years ago. In 1889, 47,000 lbs. or about one carload was produced. In 1917 the world's estimated production exceeded 382,000,000 lbs. and would require a train of 8,000 cars, a train nearly ninety miles long, to load it. Needless to say this increase of 8,000 fold in thirty years is far ahead of any other metal and proves that specific uses have been found for aluminium in which it is a strong competitor of the older metals.

To a great extent the production has been accelerated by the war; indeed the present output is much greater than in 1914. Many hundred tons of aluminium sheets have been used in the construction of aeroplane fuselages and in the structure of airships. Other applications have been for the manufacture of canteens and field utensils, binoculars and instruments, also bullet tips, shell fuses and not least as an explosive. It is interesting to note that many miles of scrap aluminium wire taken down from a transmission line near Montreal were unstranded, straightened, drawn and headed into bullet tips which were afterwards turned to good purpose. Similarly considerable quantities of scrap material were turned into powder for use as an explosive. As we have already seen, aluminium oxide is very difficult to reduce to the metal; conversely aluminium in a finely divided form is oxidised very readily and in combination with an oxidising agent the action takes place with violence. It is only necessary to bring together aluminium powder with ammonium nitrate and to ignite them with a special detonator to produce an explosion. The same action slightly modified is used in the well known thermit process in which this oxidation of a small

*Lecture delivered to the Electrical Club of Montreal by Ernest V. Parnell, of the British Aluminium Co., Ltd.

quantity of aluminium after being once started by a cartridge generates sufficient heat to melt the iron contained in the crucible.

The Manufacture of Aluminium Wire

It will be interesting to follow briefly the operations in the production of electric wire and cable in which aluminium is becoming so widely used at the present time. The metal leaves the electrolytic furnace in the shape of a block. These blocks or pigs are all analyzed and graded according to purity. In order to secure the necessary conductance a purity of well over 99 per cent must be attained and lower percentages, although they yield metal which is actually better for some kinds of work, are not passed for the wire mill. Next the metal is remelted to enable it to be cast into shape for rolling. There are many different forms of wire billets depending upon the requirements of the mill where they are to be rolled; the larger mills will, of course, take billets 5 in. square or larger whereas smaller mills will probably specify the bars to be 2 in. or 3 in. Needless to say the best material is produced by rolling down the largest possible billet which the capacity of the mill will permit.

It is usual to roll square billets rather than round because the former shape will be worked up more thoroughly and will give wire of greater tenacity. A typical wire bar into which the metal is cast is four inches square and weighs 84 lbs. This is broken down and run down hot through a great many passes the material changing its shape continually while rolling so as to be thoroughly worked. It finally emerges as a rod $\frac{3}{8}$ in. diameter and about 650 feet long ready for drawing. Operations in the wire mill are similar to those on copper. However, the aluminium rods have the peculiarity of being free from scale and do not have to be tumbled. Furthermore it is possible to draw aluminium nearly three times as far as copper without having to anneal it. The reductions correspond to the numbers on the B&S scale and the speed depends upon the tensile qualities required in the finished product. Since aluminium is much more flexible than copper it is usual to strand up wires of larger diameter and the sizes stranded are from 10 to 16 B&S on the average. The finished wire is tested for conductance when drawn. Now the conductance of a unit cube of aluminium will vary from 58 to 62 per cent. that of standard annealed copper in the same size and is, of course, dependent on the temper of the wire. Very soft aluminium will be higher than 62 per cent. and very hard wire only about 58 per cent. It stands to reason then that there is no such thing as standard conductivity unless the tensile strength of the wire is also defined as well as the size but it is sufficient to adopt the usual figure of 60 per cent. with a tensile strength of 24,000 lbs. per sq. inch. If we are going to replace a copper wire on an overhead line with an aluminium conductor the latter will be nearly 66 per cent. larger in area and 29 per cent. greater in diameter. In other words it will be nearly two numbers lower on the B&S scale so that a No. 10 B&S copper wire would be replaced with a No. 8 aluminium.

Aluminium cables are stranded and reeled just like copper; they are naturally easier to handle during erection because of the lighter weight and greater flexibility. There is one disadvantage, however. When aluminium cables are strung on a long span tower line in the same way as copper they will be found to sag from 25 per cent. to 50 per cent. more owing to the fact that they cannot be pulled up as tightly. This factor has had little effect in climates where sleet loading does not have to be allowed for but in the northern United States and in Canada the extra sag on aluminium lines has led to the use of higher and more expensive towers. This has sometimes led to the economy effected by using aluminium instead of copper being entirely eliminated due to the extra steel.

For a long period experiments were made to determine means for the production of a conductor which would sag less than aluminium. In the first place the metal was very carefully rolled and drawn so that the tensile strength instead of being 24,000 lbs. per square inch was as high in some cases as 35,000 lbs. This, however, meant costly manufacturing operations and lower conductance. Then alloys of aluminium with copper and aluminium with nickel were tried out. These alloys yielded a tensile strength as great as copper but the conductance was very much lower than pure aluminium and a greater disadvantage was found in the deterioration which took place after exposure to the weather. Next the success which attended the use of copper-clad steel wire induced the manufacturers to experiment in the casting of a compound aluminium-steel billet and rolling and drawing down the compound wire. Unfortunately this did not work out as satisfactorily with aluminium as with copper. In the meantime, however, tests had been made on a cable consisting of aluminium strands laid around a core of steel wires. This type of conductor had a period of trial in one or two installations on the Pacific Coast for several years before it was advertised and in every way its durability was thoroughly proved. Aluminium-steel conductors are now the standard form of cable for long span high tension lines.

At first it was believed that the combination of aluminium and steel would lead to considerable trouble. It was thought that there might be corrosion between the two metals due to the ingress of moisture. However, this has not been reported. The steel wires are always double galvanized and impregnated with fish oil. Now the zinc coating on the steel works very well in contact with aluminium because it will be found from a chemical table that the two metals are very nearly the same in the positive series; in other words there will be little or no galvanic action between them even in the presence of moisture. Another objection which was urged was that with increasing temperature the aluminium would expand faster than the steel and would tend to open up the cable in birdcage fashion; this also has been found to be a mistake. As a matter of fact when properly dead-ended the two metals will expand and contract exactly the same as each other and will share the load between them so that there is no relative movement.

So the net effect is as follows: we obtain a conductor which is about thirty-five per cent. heavier than aluminium and costs four or five per cent. more. But it will have a sag on long spans of fifty per cent. less; in other words the towers will be from 10 to 30 feet shorter and a corresponding quantity of steel will be saved from the line construction. The cables can be strung tightly with short crossarms and a minimum risk of swinging together.

Used for Switchboard Work

Since many thousand tons of aluminium have been used for overhead transmission it is not surprising to find that the metal has also been employed in other directions as an electrical conductor. For instance, in England there are many instances of sub-station busbars and switch connections being installed in the light metal. Here a new aspect presents itself. It is not the drop in volts which determines the size but the temperature rise. Now we have already seen that aluminium has a thirty per cent. greater diameter than the same conductance of copper; in other words, it has a thirty per cent. greater surface to radiate heat. So that the temperature rise will be lower, or alternatively for the same temperature rise a smaller conductor can be used. Following this out we find that for switchboard work one pound of aluminium goes nearly as far as two and a half pounds of copper.

A special application of aluminium may be here men-

tioned, that is, in the form of round rod connections for battery rooms. Sulphuric acid vapor is one of the agents which have very little detrimental effect on the metal; several battery rooms have, therefore, been connected up with aluminium throughout and give very good service. The great advantage in the use of round rod is that it can be butt welded. All that is necessary is to square up the two ends of the rod which are to be jointed and face them together in the flame of a gas torch. In a minute or two the metal will begin to soften and the ends are then firmly pressed into contact; the action squeezes out the oxide and a perfect joint with 100 per cent. conductance is the result. The same process is used with wire and many other forms of the metal but it should be remembered it is not permissible for cables to be used for overhead work because the joint in the wire will be annealed and not stand up to the same stress as the rest of the cable.

When operating voltages rose from 60,000 to 100,000 and then to 150,000 volts a trouble arose which soon began to be a serious operating problem. I allude to the phenomenon of corona discharge. In a few words it may be expressed as the breakdown of the air as an insulator and the production of a discharge from the wire, leading to a definite loss of energy. This discharge will take place at a higher or lower voltage according to certain conditions which is the size of the wire. The smaller the wire the lower will be the corona voltage. Now if the corona voltage is lower than the operating pressure there will be a loss of energy and some artificial means may be necessary to raise the corona voltage. This is done automatically by the use of aluminium and while there might be a considerable corona with a copper wire it will probably be found that the 30 per cent greater size of the aluminium will eliminate the corona altogether. This is generally regarded as being a matter affecting only high tension lines but it also enters into switchboard connections and insulated cables.

There are many engineers who have been accustomed to look upon aluminium as a perfectly good material for an overhead cable but who imagine that the metal cannot possibly be adopted for underground work for economic reasons. Now as a matter of fact aluminium cables have been employed for underground insulated work not only for low voltages but for transmission work running into 30,000 volts. Aluminium is found to give good results for two different reasons. In the first place on low tension cables such as are largely used in Europe for street railway feeders underground the section of metal is large and the insulation, usually paper with a lead sheat or bitumen, is not very costly. In this case it has often been found that the insulated aluminium cable, complete, is as much as 12½ per cent. cheaper than copper. Again when very high voltages are considered the larger size of the aluminium core leads to a lower potential gradient in the dielectric which is practically the corona limitation coming in again. In other words less insulation is required for this larger core and the cable is again cheaper.

It is not necessary to say very much more to demonstrate that aluminium is worth the consideration of every electrical engineer but, of course, it must be brought into comparison with copper in every specific case to show just whether it is an economic proposition. In earlier days it was objected that the supply was too uncertain to figure upon but at the present time when annual production of the white metal is 400,000,000 lbs. per year this objection has no weight.

The Interborough Rapid Transit Company, New York, has recently placed in operation at its 74th Street power house, a turbine rated at 60,000 kw. capacity continuously, and 70,000 kw. for two hours; it is, therefore, the most powerful in the world. It has three elements, one high pressure

and two low pressure, and is the first triple cross-compound turbine to be placed in operation.

The new unit occupies a floor space of 52 x 50 ft., and is about 19 feet high. The high pressure element receives steam at 205 lbs. gauge pressure, and superheated 150 deg. F., and exhausts it into the low pressure elements at 15 lbs. gauge pressure. The two low pressure elements are identical in construction, and each receives one-half of the steam from the high pressure element and exhausts it into the condenser where a 29 in. vacuum is maintained. All three elements operate at 1500 r.p.m., and each drives a generator rated at 20,000 kw. continuously, 23,500 kw. for two hours, and 30,000 kw. for a half hour. The generators deliver three-phase, 25-cycle, 11,000 volt alternating current.

Bell Telephone's New Buildings

The granting of advances in telephone rates by the Railway Commission has enabled the Bell Telephone Co. to proceed with its programme of extensions. This includes a new exchange at the corner of Belanger and Boyer streets, in the north eastern section of Montreal. This office, which it is hoped will be completed by the end of the present year, is to be known as "Calumet." It is to be of the latest type of branch exchange building. Plans are also completed for the erection of a new building, to be known as "Madison" exchange, at the corner of Walkeley and Sherbrooke streets, Notre Dame de Grace, Montreal. This building and equipment will be along the lines of "Calumet." Contracts have been awarded for the completion of the 10-storey telephone building—the "Plateau" exchange—at the corner of Ontario and St. Urbain streets, Montreal. It is planned eventually to house two exchanges in this building.

Plans are being prepared for new exchanges at Chatham, Welland, Pembroke, Woodstock, Shawinigan, and Brampton.

Expansion of business at London and Brantford call for an additional storey on the telephone buildings at both places. The work is to proceed at once.

Suggested Policy of the Navy League of Canada

1. To disseminate among the people of Canada a knowledge of the necessity and use of sea power as the keystone of Empire and National defence and commercial prosperity.
2. The advocacy of a policy that Canada shall assume her proper share of the cost and maintenance of protecting her own trade routes and coast defences.
3. The advocacy of a marine policy that will tend to build up our Mercantile tonnage.
4. The advocacy of the establishment of a naval reserve force composed of Canadian officers and men who have served in either the Imperial or Canadian Naval forces.
5. The support of all just claims of officers and men of the Royal Canadian Navy and its auxiliaries with regard to pay and pensions, and that merchant officers and men in times of war be put on an equal footing with regard to pay and pensions with officers and men of the Royal Canadian Navy.
6. The support of sailors' institutes in Canadian ports to better the conditions of merchant seamen when ashore.
7. The application of steady pressure upon Parliament and the Government for a better and more efficient administration of the Department of Naval Service, and the abandonment of the present system of the portfolio of Marine, Fisheries, and Naval Defence being under the Minister.
8. The application of steady pressure upon all people enjoying the Canadian franchise to see to it that our public men and Members of Parliament insist upon it that all matters pertaining to our maritime policy shall be free from political bias.
9. The encouragement and extension of Naval Colleges and of the Boys' Naval Brigade movement, and the establishment of proper training institutions, with a view to the preparation of boys and men for a seafaring career to the ultimate end that all Canadian ships shall be manned by British-born and the elimination of aliens from the Mercantile Marine.

Pulverized Coal as Fuel for Stationary Boilers

Extracts from a Paper by Mr. N. C. Harrison Before the American Society of Mechanical Engineers.

Many engineers who attempted to burn coal in pulverized form in the early days obtained unsatisfactory results, and concluded it was "impossible." In many of the earlier trials to burn pulverized coal under boilers the method adopted was to install coal-feeding devices of some kind in the furnace as it stood, with the result that the fire bricks melted down and the tubes were plastered with unconsumed carbon, ashes and soot. So destructive were the results that we can hardly blame those making the tests from arriving at the conclusion they did. How close some were to success was not fully realized. Conditions were not ripe. Today, results are being obtained that are of sufficient importance to warrant careful investigation and consideration.

For the proper combustion of coal under boilers, there are five main points which must be given serious consideration, otherwise the burning of this fuel will not be a success. These five points are:

- (a) Coal fineness.
- (b) Size of combustion chamber.
- (c) Necessary air opening.
- (d) Proper damper regulation.
- (e) Clean tubes.

Coal Fineness

The pulverized coal should run about 96 per cent. through the 100-mesh screen and about 85 per cent. through the 200-mesh screen. If it runs below 80 per cent. through the 200-mesh screen, we notice particles of carbon flying through the air inside the combustion chamber, and these particles are not completely burned when the gases reach the tubes, and will then deposit themselves on the tubes. Also, these heavy particles in the pulverized-coal mixture will sometimes settle on the bottom of the combustion chamber and will soon build up in the shape of stalactites. This accumulation will continue to build until it comes in contact with the flame. These built-up particles will then fuse into a solid mass, which, in a very short time, will cause a shut down of the boiler to dig this fused mass out. It is, therefore, necessary, for the successful burning of this pulverized fuel under boilers, to have this coal as finely pulverized as possible.

Size of Combustion Chamber

Before installing, or considering the use of pulverized coal under boilers, we must first make a study of our boiler-house installation and know at exactly what rating we wish to operate these boilers, considering any peak load which may develop. We must then design our combustion chamber large enough to take care of the maximum loads which will be developed from our boilers at any time. After this maximum rating has been determined, we then figure our combustion chamber of a cubical capacity equivalent to approximately 50 cu. ft. per lb. of coal burned per min., or approximately $2\frac{1}{2}$ cu. ft. per h.p. developed by boiler. If we decide to run this boiler at 150 per cent. of this rating and design our combustion chamber accordingly, the efficiency will not be decreased perceptibly if the boiler is run under this 150 per cent. rating, but if we develop over a 150 per cent. of the rating, we run into serious difficulties. We have to admit more coal and air to the boiler to develop the greater rating, consequently we need more combustion space, but not having this combustion space, the flames

impinge on the brick work and cut it away very rapidly. Also, combustion is not complete at the time the gases strike the bottom row of tubes and consequently the gases will pass up the stack unburned. Efficiency is then decreased. If the gases are not completely burned by the time they reach the first row of tubes, they will not burn later on in the boiler. The size of the combustion chamber should also be so designed that the velocity of the gases should not pass through this combustion chamber at a speed of more than 6 ft. per sec. The mixture of air and coal entering the combustion chamber, as stated above, should be at as low a pressure as is possible to bring this mixture in in suspension; or, in other words, breathe it in.

Proper Air Openings

The pressure at which the pulverized coal is admitted to the furnace is as low a pressure as can be used to carry this fine coal in suspension, and is, I should say, about half an ounce pressure at the nozzle. In some installations the coal falls by gravity from the variable-speed screw conveyor, located on the bottom of the pulverized coal bin, into a fan air line which carries it into the furnace and also supplies the necessary air for combustion. Some few openings are placed in the front wall of the boiler to give any additional air which may be needed, and a few may also be placed on the side walls of the boiler to protect the brick-work at times.

In other installations the amount of air necessary to convey the coal into the furnace varies, according to the rate at which the boiler is being operated. The balance of the air to burn the coal properly is admitted through adjustable air openings in the front, sides and bottom of the combustion chamber. These openings are made adjustable and are placed on all sides of the combustion chamber to take care of the various grades of coal which may be used in the boiler plant. By properly observing the combustion in this chamber, by a little experience the fireman knows at exactly what points to give more, or less air needed for combustion.

Damper Regulation

In order to give the proper velocities of gases passing through the combustion chamber, it is necessary that we have very accurate damper regulation to take care of the various load conditions which the boiler is to supply. The damper should be so regulated that we should practically have a balanced draft inside of the combustion chamber and only a slight vacuum in the first pass, while at the damper itself we do not want more than 0.10 to 0.15 in. If we have more vacuum than this, it pulls our gases through the combustion chamber too fast, causing them to be unburned before reaching the first row of tubes and will then build up very fast on the outside of these tubes. This very small draft needed at the base of the stack will allow us to operate boilers using pulverized coal with stacks of about 30 to 35 ft. in height.

Clean Tubes

In order to get the maximum evaporation from any boiler it is necessary that the tubes be kept clean, both inside and outside. The keeping of the tubes clean inside is a question of the proper quality of water and has nothing to do with pulverized coal. The keeping clean of the out-

side of the tubes is very necessary with the use of pulverized coal as a fuel, and they should be blown by means of mechanical soot blowers at least every six hours, and oftener if it is necessary. Also, once every 24 hours by means of a hand-lance steam jet we should blow the bottom of the first row of tubes. These are the tubes in which the gases come into contact first after leaving the combustion chamber. This material can be blown off easily if the combustion chamber has been properly constructed and if they are blown regularly as needed. But if they are not blown regularly this material builds up and accumulates very fast and in time will become fused and cannot be blown off.

Removal of Ash

Another item which might have been included in the five main points above, and might have been called the sixth point, is the removal of ash which deposits at the bottom of the combustion chamber. As spoken of above, this ash should be removed at regular intervals, which intervals will be determined by the amount of ash in the original coal. If we do not remove this ash regularly, it will build up until it comes in contact with the flame, when it becomes fused and has to be dug out. But if removed at regular intervals, it can be easily raked out with the ordinary boiler-room ash rake and will not consume more than half an hour per 24 hours, and will not interfere with the operation of the boiler while this is being done.

The following are some advantages of pulverized coal as a fuel for boilers over stokers:

usable is obtained when burning coal in pulverized form.

(a) Much wider variation in the quality of the coal. Practically any and all grades of coal can be burned in this form with economy. No stoker will satisfactorily handle all grades of coal. Therefore the use of pulverized coal will largely overcome most trouble due to poor coal, and it is particularly desirable for this reason alone.

(b) The ability to take care of peak loads almost instantaneously. In other words, a pulverized-coal burning system is much more flexible than a stoker installation. Its flexibility approaches that of oil or natural gas.

(c) The amount of coal that can be burned per sq. ft. of grate surface on stokers is limited so that for increased capacity the boiler setting must be spread out to cover more area. When using pulverized coal this condition does not exist, for proper furnace conditions can be obtained by increasing the height of the boiler setting or the depth of the combustion chamber.

(d) By throwing a switch the entire firing operation ceases; an advantage in case of accident or emergency.

(e) Ash is in much better condition to handle. The ash is in the form of a dust or slag depending upon its melting point. This helps to maintain constant furnace temperature as there are no interruptions to firing conditions on account of cleaning fires.

(f) Since there are no grates used when the fuel is burned in pulverized form, we experience no clinkering of grates, as in the case of stokers, particularly after operating at maximum rating.

(g) Pulverized coal is fired dry, containing less than 1 per cent. of free moisture, whereas coal burned on stokers may vary anywhere from 1 to 10 per cent., of free moisture as fired.

(h) Considerable less excess air is necessary for complete combustion. This item is of the utmost importance when making comparisons. Less excess air means less power for furnishing air supply particularly where forced draft is used. With less excess air the stack losses are less. Lower grades of coal fired on stokers require more excess air as it is quite difficult for the oxygen to get in close contact with the combustible. An air supply sufficient

to furnish all the aid for combustion should be available, although at times only 50 per cent. of the air is necessary to be injected into the furnace with the coal, the balance being supplied by the induction action of the burner or drawn in by the stack draft through the various adjustable openings in front and sides of combustion chamber. The air going into the furnace should be under control to permit close regulation under all conditions of firing. Less draft is required for pulverized-coal-fired furnaces.

(i) All the combustible in the coal is consumed when it is burned in pulverized form, providing the furnace capacity is not exceeded. None of the combustible goes out into the ash pile and therefore fires are eliminated in the ash pile.

(j) There is less erosion from sulphur on the boiler due to less moisture in the coal as fired, therefore high-sulphur coals can be burned more readily and without serious results.

(k) With furnace properly proportioned and with properly designed burning equipment smokeless operation may be maintained indefinitely. This is due to complete combustion of all the particles of coal before coming in contact with the cold surface of the tubes of the boiler.

Points to Keep in Mind

The following few points must be kept in mind for the successful burning of pulverized coal under boilers:

(a) A boiler using pulverized coal should have as few burners as is possible consistent with good regulation. The burners must be proportioned for the maximum rating of the boilers, and they must be adjustable. Simplicity of design is desirable. It has been found much more desirable to introduce coal into the furnace as far away from the side walls as possible so that the rapid continuous expansion of the gases will not develop high velocities in close contact with the furnace refractories. Furnaces under boilers should be proportioned so that the velocity of the gases should not be excessive, particularly at the smallest cross-sectional area of the furnace. Vertical baffles should replace all horizontal baffles.

(b) A boiler of any size can be fired successfully with pulverized coal. Various designs and makes of boilers can be readily arranged for pulverized-coal firing, but those containing the smaller percentage of space for the lodgment of ash are preferable.

(c) Feeders for regulating the flow of pulverized coal to the furnace must be designed so that at all times the variation in quantity will be directly proportional to the speed of the screw and no flooding allowed. The speed of the feeder should be so regulated that operating at its maximum r.p.m. the supply of pulverized coal to the furnace will not exceed the capacity of the furnace. Soot blowers should be installed in settings where pulverized coal is used.

(d) The equipment for using pulverized coal is standard for any grade of coal so far as handling, preparing and delivering to the furnace is concerned. Only a slight change is necessary in the furnace to take care of coals of very low volatile content, such as anthracite, culm and coke breeze, and increased drying capacity is desirable when lignite coal is used. With stokers this is not the case as the varying quality of coals require different type stokers to obtain highest efficiency.

(e) The labor required to operate a pulverized-coal installation may be of higher class but the number of men required will be less in the larger installations than that required for a stoker installation, thereby affecting a saving in the labor charge in favor of pulverized coal.

An Actual Test

The following is a report of a test made on a 468-h.p. boiler using pulverized coal as fuel. This installation is

noteworthy not only by reason of the high efficiency obtained, but also because of the fact that it has made clear some of the conditions necessary for the successful operation of boilers utilizing powdered fuel.

When the boiler was first put into operation, a number of undesirable conditions resulted. An insufficient air supply caused high-furnace temperatures resulting in fusion of the ash particles and a consequent accumulation of slag between the tubes, on the furnace walls and in the ashpit. The removal of the molten slag presented considerable difficulty. It was also found that the combustion chamber was of insufficient size. High gas velocities resulting from insufficient air in the chamber tended toward destruction of the refractory surfaces of the furnace.

A new furnace was, therefore, designed. The combustion chamber was enlarged and a regulated air supply was provided for by means of a number of auxiliary air openings equipped with dampers. The accumulation of slag in the pit was prevented by raising the point of admission of the fuel into the furnace. As a result the flame path has been raised above the base of the pit, hence particles of ash dropping from the flame are not fused. The ash, therefore, can be drawn from the pit in the form of a powder and small slugs of slag. Analysis has shown that the ash contains practically no carbon.

Having established satisfactory furnace-operating conditions, a series of efficiency and capacity tests were conducted preliminary to proving the contract guarantees. The brickwork was then given a thorough trial by carrying the boiler at a continuous rating of 180 per cent. over a period of several days. On August 12 and 13 a final efficiency test, the results of which are given below, was run. The boiler is a three-pass water-tube boiler, equipped with a superheater.

Log of Test of a Pulverized-Fuel-Burning Stationary Boiler.
Date August 12-13, 1918.

Date August 12-13, 1918.				
Make of boiler				Edge Moor
Rated h.p.				468
Heating surface, sq. ft.				4685
Time fired or test started				11.15 a.m. 8/12/18
Time fire out or test finished				11.15 a.m. 8/13/18
Duration of test				24 hr.
	Maximum	Minimum	Average	
Temperature of boiler room (deg. fahr.)	99	85	93.3	
Temperature of feedwater	168	135	151.2	
Temperature of steam (deg. fahr.)	477	427	448.7

Coal used in drier, lb.	1,140
Motor operation	449.3 kw.-hr.
Coal equivalent at 3 lb. per kw.-hr., lb.	1,348
Total deduction, lb.	2,488
Resulting net efficiency, per cent.	81.1

*No deduction made for stand-by losses in drier.

Pulverized Coal vs. Mechanical Stokers

At this same plant are other boilers fired by one of the most efficient types of underfeed stokers. A comparison is made below between results of above test and tests made on the stoker-fired boilers. Fuel-preparation costs will first be considered. In the case of powdered coal this can be classed under three general divisions:

(a) The cost of crushing the coal. This expense is the same for pulverized-coal equipment as for stokers.

(b) The cost of drying and pulverizing the coal. Although no cost records are available at present, it is estimated that 32 cents per ton will cover this preparation cost on a 200-ton-per-24-hr. plant using bituminous coal containing about 12 per cent. moisture.

(c) The maintenance costs of the drying and pulverizing plant. This unit has not been determined from actual experience; however, it is estimated that 3 cents per ton will cover the maintenance. In stoker practice the maintenance cost per ton of fuel fired is close to 5 cents per ton.

Summarizing the above facts it is evident that, with fuel at \$5 per ton, the gross efficiency shown by the pulverized-fuel boilers will have to exceed that shown by the mechanical-stoker-fired boilers by 6 per cent. in order to offset coal-preparation costs. A 6 per cent. deduction from a gross efficiency of 85.22 per cent. results in a net efficiency of 79.22 per cent. for the powdered-coal burner. In stoker practice the maximum attainable gross efficiency at any of our plants has been 80.54 per cent. Deducting the 2.5 per cent. for auxiliary uses, the resulting net efficiency is 78.04 per cent., which is lower by 1.18 per cent. than the figure obtained in pulverized-fuel practice.

Other advantages resulting from the use of pulverized fuel are summarized herewith:

(a) Continuous boiler operation at a uniform rating as well as a constant efficiency is made possible. At no time is there a loss in capacity due to the clinkering of coal on the grates or the cleaning of fires, as is the case in stoker practice.

(b) Heavy overloads can be taken on or dropped off in a very brief time through adjustment of the coal feeders and the furnace drafts.

(c) From 97 to 98 per cent. of the combustible in the coal is utilized, regardless of the quality of the fuel.

(d) The ash-handling costs are reduced to a minimum due to the reduced volume.

(e) The banking conditions when operating with pulverized coal are somewhat different from those obtained in stoker practice. By stopping the fuel supply and closing up all dampers and auxiliary air inlets a boiler can be held up to pressure for about 10 hours. The furnace brick work having been heated to incandescence during operation gives off a radiant heat which is absorbed by the boiler rather than being sent out through the stack. The ease of controlling the fuel, feed and drafts, the ability to take on heavy overloads in a brief time, the thorough combustion of the coal and the uniform high efficiency obtainable under normal operating make pulverized coal a most satisfactory form of fuel for central station uses.

The full story of maintenance expense is only partly known as yet, however. Indications are that no unusual difficulties will be met. The cost of fuel preparation and

labor for operating a boiler room fully equipped with pulverized-coal-burning boiler will be a question for the engineer to decide for himself according to his particular conditions. If properly installed with respect to capacity of storage, size of drier and pulverizers, and on a sufficient number of boilers to properly and fully employ the minimum number of men, the pulverized-fuel installation will undoubtedly be more advantageous. The main item that must be borne in mind by engineers is that the ease with which a high efficiency is obtained and the constant nature of that efficiency, as compared to the lack of constancy of efficiency in a stoker-fired boiler, unless very closely supervised, is the one factor about the burning of pulverized fuel which justifies its use. There is no doubt that with a well-equipped plant burning pulverized fuel, having all the necessary recording and indicating instruments to guide the operators in maintaining the proper conditions, a lower cost of generating steam will be possible than has heretofore been the case in any type of equipment.

Sherbrooke's Street Railway on Service at Cost Basis

The Sherbrooke, P.Q., Council have passed a by-law amending the agreement with the Sherbrooke Railway & Power Co. The by-law provides for an arrangement by which the city will do certain paving work, the cost to be reimbursed by the company. The fares are to be as follows: From 6 a.m. to 12 p.m. 8 cents; or four tickets for 25c; from 12 p.m. to 6 a.m., 15c cash; children under 14 years, 4c cash or 8 tickets for 25c. These fares are to remain for 12 months, and are to be subject to revision every 12 months at the request of either the city or company, the Quebec Public Utilities Commission to decide in case of disagreement. The company is free from the cost of snow removal for a period of five years. The company agrees to extend the system at once, and to double track a portion of its lines. The linesmen of the city of Sherbrooke electrical department went out on strike for higher wages; this has been settled, the men now receiving from 35c to 40c an hour, with time and a half for night work.

Electric Arc Welding

The Westinghouse Company has just recently issued an elaborate publication covering the process of electric arc welding and the necessary apparatus required for this process. This publication compares the different processes of welding, such as autogenous welding, forge welding, oxy-acetylene welding, thermit welding, and outlines the advantages of electric arc welding over these as follows: 1, economy; 2, ease and convenience of application; 3, speed of operation; 4, reliability of results; 5, reclaiming defective material; 6, safety; 7, conservation of material; 8, less skilled labor required. The field for electric arc welding is unlimited and the process has made enormous strides during the last few years until now it is widely used throughout those branches of the metal industry in which work is done on iron or steel in rolled, cast or fabricated forms.

The Maine and New Brunswick Electrical Power Co. have let the contracts for an additional unit at their development at Tinker Station, N.B. This will make the fourth unit. The Foundation Co., Montreal, will enlarge the dam and power house, and construct a tunnel and new steel penstock. The water wheel will be of 2400 h.p., 400 r.p.m., complete with Lombard governor, working under a head of 72 feet, and will be supplied by the Canadian Ingersoll Rand Co., Ltd., Sherbrooke and Montreal. It will be direct connected to a 1500 kv.a. generator, to be supplied by the Canadian General Electric Co.

David A. Starr Made World Reputation as Manager of Clyde Valley Electrical Company

We regret to report the sudden death on June 23rd of Mr. David A. Starr, general manager of the Clyde Valley Electrical Power Company, Glasgow, at the age of 61. He had been in failing health for the past eighteen months, but had recently returned to business after four months spent in the United States, Cuba and Jamaica. Mr. Starr, who was well known in electrical engineering circles in Great Britain, as well as in Canada and the United States, was born in Halifax, N.S., and, after serving his apprenticeship there joined the civil engineering staff of the Canadian Pacific Railway Co. Subsequently he turned his attention to electricity, and joined the staff of the Thomson-Houston company at their Lynn works in the States, returning later to Montreal as sales manager to the Royal Electric Company. His subsequent Canadian experience covered electric tramways and light railways.

In 1901 the British Westinghouse Electric & Manufacturing Company, Ltd., secured his services for their Trafford Park works, Manchester, and in 1903 he was ap-

The late Mr. David A. Starr

pointed general manager of the Clyde Valley Electrical Power Company. The erection of the company's power stations, and the laying down of their large plant and comprehensive system of mains, were carried out under his supervision, and the present development of the power supply business in the west of Scotland, together with the position of his company as one of the largest in the kingdom, must be attributed to a large extent to his unflagging zeal and energy, and to his sound views on the future of the industry. Mr. Starr was a past-president of the Scottish Section of the Institution of Electrical Engineers, and was closely associated with the work of the Association of Electric Power Companies.

Mr. Starr, who was a son of the late Mr. John Starr, Halifax, Nova Scotia, is survived by a widow, three daughters, and one son. Mrs. Starr was Miss Ella Brown, daughter of Mr. Alexander Brown, Prince Edward Island, and the two elder daughters are Mrs. J. C. Manson and Mrs. H. G. Good. The only son, Alexander, is, since demobilization from the army, associated with his uncle in the business of John Starr, Son & Company, Halifax, N.S.

The Contractor-Dealer

Channels of Distribution Between the Manufacturer and Consumer—Contractor-Dealer a Dominant Feature If, and When, His Sales Policy Becomes Aggressive

By Mr. Samuel A. Chase

The channels of distribution in the electrical industry are indefinitely marked with trade beacons of (1) trade organizations, (2) proper trade differentials, (3) proper codes of practice and ethics, supported by absolute knowledge of what each of these beacons means to the captains of our industry. It reminds me of the mariner who endeavors to pilot his ship through a river which was not clearly marked with beacons of safety.

In considering this subject three important factors should properly enter into the discussion, viz.:

- (1) Economic distribution.
- (2) Effective distribution.
- (3) Adequate distribution.

The product of this cargo to be distributed from the manufacturer to the consumer is made up principally of merchandising or resale electrical appliances and supplies and does not include, in its bills of lading, lighting or power apparatus.

The various channels of distribution in the past from the manufacturer to the consumer may be divided into the following groups:

- By the manufacturer direct.
- By the jobber—wholesaler.
- By the Manufacturer's Agent.
- By the Central Station.
- By the Hardware Merchant.
- By the Dry Goods Store.

By the Drug Store, and in some instances by various other merchants not strictly in the electrical supply business.

- By the Contractor-Dealer.

The Manufacturer

The manufacturer has frequently made the mistake in the past of being allured by the temptation to obtain the middleman's profit, and has taken small orders direct from the consumer, at an apparent profit, but has learned by costly experience that this so-called profit is wiped out by the cost of obtaining and handling the orders. The result is not only a net loss in money, but a disturbed and unhealthy condition in the trade, but it has, in some instances, taken years of experience to teach some manufacturers the wisdom of a policy of selling his merchandising product to the consumer through the middlemen, recognizing the service rendered by the jobber and the contractor-dealer.

The manufacturer has, in some instances, chosen the direct route to consumers in the past due to the uneconomic, ineffective and inadequate distribution through other channels and a hesitancy on the part of the middleman to create a sufficient demand for the goods manufactured and although a definite sales policy has been adopted by some manufacturers of selling direct and through the middlemen at the same prices, their direct sales exceed all others by a

large percentage, notwithstanding the local influence of the middleman and the cargo close at hand.

I will venture to state that the average manufacturer will welcome the day when it will be possible to economically and efficiently distribute his merchandising product exclusively through the electrical jobber and retailer (central station and contractor-dealer) but these channels are not yet deep or broad enough or sufficiently safe and efficient to warrant any manufacturer with a large sales organization in the field to sell exclusively through the jobber and retailer.

The Jobber—Wholesaler

The jobber or wholesaler has done in the past, and in some instances, at the present time, still does a retail business in addition to a wholesale business, and sells to other jobbers, to central stations, to contractor-dealers and to consumers—and, in some instances, I regret to state, sells to consumers without recognizing, in the form of a differential, the service rendered by the contractor-dealer; in other words, sells to the consumer at the dealer's price, which practice is not only unethical, but demoralizes the contractor-dealer business to such an extent that it makes that class in the industry seemingly distrustful and quite naturally has a tendency to prevent his engaging in the retail business, hence retarding sales and expansion.

The jobber of the past has been somewhat like many manufacturer's agents, and has shipped an order calling for a miscellaneous lot of goods from the four winds of the earth direct from the various manufacturers to the contractor-dealer or consumer because of not carrying a sufficient stock in his warehouse.

Cross arms from the State of Washington.

Pins and brackets from North or South Carolina.

Pole line hardware from Illinois and Pennsylvania.

Bare and insulated wires from Massachusetts or New Jersey.

Wiring devices from Connecticut or New York State.

Bell wiring appliances from Pennsylvania or New England, causing delayed and expensive shipments. But the jobber of to-day assembles all these goods in his own warehouse and distributes for the manufacturer complete, in one shipment, frequently the same day the order is received, which is of great advantage to the contractor-dealer. Therefore the jobber can be the natural, economic and efficient channel of distribution from the manufacturer to the contractor-dealer.

The Manufacturers's Agent

The manufacturer's agent's policies vary. Some carry a small stock and ship and invoice customers, while others carry no stock and are simply order takers for the manufacturer; some sell indiscriminately to jobbers, contractor-dealers, and consumers, and should, in reality, be classed as salesmen for the manufacturer, who has no sales organization in the field.

Central Stations

Central stations have been pioneers in the sale of and distribution of incandescent lamps, and that channel was marked with beacons of free renewals and cut prices, alluring the industry not to a haven of safety, but to a rock-

bound coast of disaster. Now, the channel has changed to the jobber, contractor-dealer and central station, with the percentage clearly marked with beacons of ethical merchandising and intensive selling, producing absolute fairness in competition between the competing groups—and the contractor-dealer with a well-located, attractive retail store now plays an important part in the channel of distribution of lamps from the manufacturer to the consumer.

The flat iron, washing machine and vacuum cleaner and other household appliances were introduced principally by the central station who did the pioneer work on these appliances as well as on incandescent lamps, and it is my belief that the central station, on account of its organization, prestige, financial responsibility and desire to add kilowatts to its lines, will always be the logical pioneer and pilot the way for the jobber and contractor-dealer on household, current consuming devices, and it would be very unfortunate to the manufacturer and to the consumer if the central station should go out of the retail business, properly con-

Mr. Samuel A. Chase

ducted on an ethical basis. Most central stations will always carry the introductory or development expense of placing new current consuming devices on the market. It is, therefore, up to the contractor-dealer to co-operate and take full advantage of the demand created.

Other Merchants

The hardware, dry goods, drug store, and other kindred merchants have probably done more to advertise electrical merchandizing products than other distributors, but I do not always approve of the character of their advertising, because, like the central station advertising, its principal story is "cut-prices." With recognized business ability, however, attractive stores and display windows and unquestionable financial standing the call of the siren has been so alluring that it has wrecked many a manufacturer's ship in the channel of distribution to the consumer.

Each of these groups, however, create and obtain a certain amount of business which ordinarily could not be obtained by strictly electrical concerns principally because these merchants make it easy for the housewife to obtain electrical appliances for the reason that their stores are attractive, located in the shopping district frequented by ladies and in charge of efficient sales organization, and they will continue to increase their electrical departments and sales and will attract the manufacturer as one of the efficient and economic channels of distribution to the consumer, unless the contrac-

tor-dealer becomes alive to the situation and the necessities of the public and parallels the methods of these merchants.

The beneficial results, through a plan of scientific merchandising, practical trade co-operation and organization advocated by Mr. Goodwin, about which you are all familiar, so ably supported by the electrical press, manufacturers, jobbers and central stations will unquestionably result in making the specialized electrical retailer, whether he be central station, jobber, or contractor-dealer, the dominating channel of distribution from the manufacturer to the ultimate consumer.

The Contractor-Dealer

The contractor-dealer has not, until recently, become a merchant, and I don't know as I can blame him, for the reason that apparently all classes in the industry have looked upon him as a necessary evil, rather than an economic necessity. All other classes in the industry have been cultivated to a high degree, but the contractor-dealer, until recently, has been allowed to drift, unaided, uncultivated, and looked upon as a parasite, superfluous in the channel of distribution and, rudderless, without a beacon light to guide him, has been wrecked on the rocks of commerce.

The contractor-dealer, because of these facts, and realizing there was no stability to the prices of merchandizing appliances or wiring devices, has not taken advantage of the opportunity presented and opened a sufficient number of attractive retail stores and the channel of distribution from the manufacturer to the consumer via the electrical dealer route has made it difficult rather than easy for the housewife to purchase electrical appliances.

Manufacturers and jobbers alike have sunk the contractor-dealer ship in the past through unethical and other unbusinesslike methods, frequently rendering it impossible for the dealer to distribute to the consumer at a profit, and the goods purchased from the manufacturer for the purpose of distributing to the consumer remain on the shelves, slow moving, and often become obsolete because of these unethical methods.

Channels of distribution change like rivers and we cannot force distribution from the manufacturer to the consumer through uneconomic channels because, like rivers, such a distribution will back up and create a new channel. Some rivers don't change their channels, but the channels of navigation sometimes change and so does the channel of distribution. However, just as the channels of navigation in a river change from time to time, due to natural elements, farming sandbars, sand pits and other elements dangerous to navigation, which may be changed by design through medium of engineering talent and modern machinery by the application of the dredger, tide walls and jetties, so may the channels of distribution of electrical merchandise be changed by the application of scientific merchandising methods directed by the best thought and activity of the contractor-dealer.

I am firmly convinced that by an aggressive sales policy by the contractor-dealer in co-operation with the jobber, by maintaining high class specialty shops, active interest in his association and by the most friendly relations with the manufacturer, central station, consulting engineer, builder and architect, the channel of distribution of the contractor-dealer will gradually become wider and deeper until he will become a dominant factor in the percentage of materials distributed through his channel and will be a powerful factor in the future in molding the policy of the manufacturer towards a definite decision to recognize the contractor-dealer to a greater extent in the future as the most economic and effective distributor of re-sale products.

The Open Meeting

The "open meeting" of the contractor-dealer is a necessity and is commanding the respect of manufacturers, job-

bers and central stations, and through the knowledge these groups obtain of the problems of the contractor-dealer, to this extent will they be able to lend co-operation, thereby causing to flow an increasing percentage of merchandise through the channel of the contractor-dealer.

The trade, like the flow of a river, seeks the channel of least resistance—the better business man the contractor-dealer develops to be, the more prominent the location of his store, the character of his store, the support he gives to his trade associations, the manner in which he conducts his trade association, the character of officers of his association, the conduct and manner of presentation of his trade problems through committees when dealing with the manufacturer or jobber, all tend toward removing barriers and resistance and aid in directing the flow of trade through the contractor-dealer channel.

Now, the manufacturer is faced with the choice between certain channels for the distribution of his product—in one channel he has the palatial department store, well managed, with unquestionable credit standing—then he has the central station and the jobber, and against this he has the contractor-dealer, who, in the past, has not always appealed to him in a favorable light as compared to the other channels just mentioned, but with the methods they are now employing, with attractive retail stores, located conveniently for the buying public, intensive sales methods, improvement in organization, proper presentation of problems through able committeemen, preventing forcible rather than arbitrary arguments to attempt to force the flow of trade, the contractor-dealer is every day commanding a higher respect from manufacturer, jobber and central station, and is causing them all to think and to think hard, which must result, if they continue along these constructive lines, in causing an increasing percentage in business flowing from the manufacturer through the jobber-contractor-dealer channel.

In conclusion I would suggest that the channel of distribution in which the contractor-dealer navigates be labeled:—

- Organization,
- Co-operation,
- Ethical Merchandising Policies.
- Determination,

and with these slogans properly applied there can be but one answer, and that is the contractor-dealer ship will be the flag ship and lead the squadron through the channel of distribution from the manufacturer and jobber to the consumer.

Big July Meeting of Hamilton District Electrical Association

The Hamilton District Electrical Association held a meeting at the Royal Connaught Hotel on Wednesday, July 9. A large number of members were present. Mr. K. A. McIntyre addressed the members regarding the National Association of Electrical Contractors and Dealers' Convention to be held at Milwaukee July 14-18. At the conclusion of Mr. McIntyre's remarks the Association appointed Mr. L. H. Lander, Mr. J. A. Dynes and Mr. V. K. Stalford as delegates to this convention. The Open Price Plan was discussed at great length; it is expected, through the discussion held, that greater use will be made of this plan in the future, all the members present signifying their intention to submit all tenders issued by them to the secretary of the Open Price Plan.

Mr. Frank T. Groome has resigned his position as sales manager of the Benjamin Electric Manufacturing Company of Canada.

Lamps—The Sugar of the Electrical Business

Lamps are to the electrical trade what sugar is to the grocer. They are a staple—a necessity. Quite naturally anyone with any kind of an electrical retail business wants to handle lamps. Also certain groups in the trade think at times that they should be named the retail lamp distributors for local territory to the exclusion of other groups which also want to handle lamps. And so we have what is coming to be known as the lamp situation. Lamp distribution presents, therefore, a problem which the industry must solve. No single group in the industry working alone can solve it. Everyone will have to pull together to make it a real solution—a solution which will insure the public maximum lamp service and the industry maximum economy.

In the interests of this getting-together it might be well, therefore, to review the thoughts of the leaders of the various groups. Everyone ought to know what the others are thinking and a fair exchange of views ought to help untangle some of the present muddle. But first let us name the groups that have an interest in lamps. They are: The contractor-dealer, the central station, the non-electrical merchant handling lamps, the electrical jobber and the lamp manufacturer. All must be considered in addition to the public.

The Contractor-Dealer

The contractor-dealer's point of view is somewhat unique in that he, in most instances, until recently had very little point of view to speak of. He has not been, in the past, a real merchant. Now he has come to the conclusion that he wants to be a merchant. He feels very strongly on this point and it is his intention to show some folks who have maligned him in the past that he can conduct himself as a legitimate and successful merchandiser. He recognizes, however, the very great difficulty of conducting a retail business without handling any staple line. He recognizes that one very desirable staple line from the standpoint of profit and steady volume is lamps. He feels that he is very close to the public and that this will help him sell lamps. He feels that his contact with users of electric service in the capacity of adviser on home electrical needs and seller of electrical equipment gives him a hold on people that he should be permitted to utilize in selling lamps. He feels that the central station's main job is to sell electric service and that the central station can cede him the lamp business in return for the very material help he can be to the central station in assisting it to maintain amicable public relations. The dealer, therefore, very generally blames the jobber for the participation of the hardware and the drug man in the present scheme of lamp distribution. In some cases he even thinks the manufacturer should aid him financially in his local advertising, in order to assist in his distribution of lamps. In isolated cases the contractor-dealer is at present doing some rather wild thinking, but almost everywhere he is making his claim that he wants to be the retail merchandiser of lamps and he wants that very badly. So much for the contractor-dealer.

Traditions of Central Station Selling

Now the average central station man incorporates considerable tradition in his thinking on the lamp question. There was a time when the central station had a very real need for controlling lamp distribution among its customers. The manufacture of lamps at that time was not an exact proposition, it being impossible to produce within close

limits lamps capable of being operated at a specific voltage. This situation absolutely does not exist at present, owing to the introduction of the tungsten lamp which can be manufactured to operate within very close limits. During the early period the central station of necessity acquired control of the lamp distribution, and in many cases it still holds the reins. That it has not released its hold appears to be largely a matter of local conditions. There has been some feeling also that control should be retained until it was certain that some other able agency was really ready to handle lamp sales.

The central station man knows that he has less need to control the lamp situation now. What he does want and has a perfect right to want and get, is a full and satisfactory assurance that all sockets on his lines will be filled. This would certainly not be the case if lamp distribution were left to any hit or miss scheme.

The Non-Electrical Lamp Distributer

One of the most interesting characters in this lamp situation is the non-electrical merchant who in some way has begun to handle lamps. The hardware merchant is easily typical of this class. Possibly he handles his lamps in connection with his cutlery department. He no doubt started out with a \$300 contract which gave him a profit of only 17 to 20 per cent., perhaps less than his overhead. He took it on, however, to give it a trial. He made a feature of selling cartons of lamps instead of the one or two which the customers asked for. He soon worked the lamp business up into a real retail trade. He probably has reached a point now where he is on a \$5,000 contract and is making a profit which he considers satisfactory, in spite of the fact that his overhead is probably more than 23 per cent., or that which the average electrical dealer assumes he has. This hardware man thinks the lamp business is a good business. He is of the opinion that if all other lines which he carries were as "clean" as lamps and carried the same profit, he would be mighty happy. He firmly believes that any electrical merchant who cannot take the same line and make money on the same scale of discounts which he has been offered is either no merchant or is trying to hog all the profits. He is not particularly interested in the difficulties of the electrical industry. All he wants is to be let alone so that he can continue to sell lamps.

Another non-electrical dealer in lamps, which in some localities should be considered, is the drug store. But upon a close analysis of the class of lamps handled by the drug stores and the class of lamp business done by them it seems only fair to say that the drug store lamp business is very generally a cut-price proposition. Moreover, the volume, comparatively speaking, is not large.

The Jobber's Viewpoint

Another interested party is the jobber. The electrical jobber's problem has been to get lamp distributors who would distribute. He believed he could not afford to be too choicy. He had to go out and find dealers who could sell lamps and who would sell them. In some places he has been forced to take on non-electrical dealers because of the lack of merchandising ability in the local electrical trade. In some cases he has been a trifle "grabby" in the matter of industrial plant business, but perhaps on the whole he has been as much sinned against by incompetence within the electrical trade as he has been sinning for the extra margin against the electrical trade.

The Manufacturer

Last but not least in this string of interested lamp people is the manufacturer. He quite naturally feels that he has a duty, not only to his stockholders, but to the

public. He wants to make money and good lamps, and to make it easy for the public to buy lamps, and for his distributors to make money. He is not particularly concerned about who handles lamps as long as they do a good job of it, except that as a matter of sentiment he would probably like to see the money stay in the electrical family. He can certainly be expected, however, to favor the dealer who proves to him as a manufacturer that he knows how to get the lamps over the counter into the hands of the public and into the sockets of the homes.

While these various branches of the industry each continue to hold their beliefs, men in other industries who know anything about the lamp situation look on in amazement and continue to wonder how we get away with it. And that, indeed, is the great wonder—how the electrical industry has managed to grow and thrive as it has, maintaining the while a system of commercial distribution that looks like a Chinese puzzle.

Solution is "Good Merchandising"

The signs of the times are encouraging, however, for it appears that something orderly will grow out of the activity of the contractor-dealer. In the days to come he will probably be a greater and greater factor in lamp distribution, but it is not to be believed that he will ever get the lamp business handed to him on a silver platter. If he wants it he will have to go out and get it. He will have to build it up. He will have to learn how to use the telephone to find out whether Mrs. Smith has empty sockets at home, and to convince her that in the interests of economy and convenience, she should fill them. He will have to learn how to use the manufacturer's literature to assist in creating a demand for lamps. He will have to learn how to write letters that will make the customer see the danger of falling down the basement stairs if he doesn't put a lamp in that cellar socket. He will have to learn how to quit kicking and how to get to work. When he does that, he will know he is the real merchant, and then the lamp situation will have been solved.

Toronto Contractors' Monthly Meeting

The Toronto Electrical Contractors held their regular monthly meeting on Thursday evening, July 3rd, Mr. Kenneth A. McIntyre, president, in the chair. The members motored out along the Toronto-Hamilton highway to the new wayside inn, near Oakville, called the Alvertonia, where they had dinner together and a good lively business meeting afterwards. Over forty members were in attendance. Mr. Stalford and Mr. Reid also motored over from Hamilton and took part in the discussions.

One of the most important matters discussed was that of the absorption of young returned soldiers as electrical apprentices. Under the Dominion government's scheme for the re-establishment of these men in some trade, a fixed sum is set aside which is paid to the men during their probationary period when, presumably, their lack of experience would make it impossible that they should earn a living wage. It appears that this condition is being exploited by certain employers who have made application for large numbers of these apprentices, simply because they do not have to pay them wages. To prevent this and also to keep a regulating hand on the number of apprentices employed, having in mind the quantity that can be properly absorbed, the Toronto electrical contractors have drawn up a recommendation to the Government covering the whole situation. This recommendation was discussed at the meeting and its wording finally determined.

The question of the proper rate to charge the customer for labor was also discussed. The practically unanimous de-

cision was that an advance of 50 per cent. over the standard wage paid the men was correct.

The Open Price Plan was reported as operating in Hamilton, where the members are gradually coming in. Toronto contractors discussed the operation of the system in Toronto and a number of members who had not yet sent in copies of their tenders definitely committed themselves to do so in future. The point was raised by Mr. Roxborough that architects to whom he had spoken seemed suspicious of the Open Price Plan and rather of the opinion that it was an arrangement to boost prices. Mr. McIntyre was authorized to get in touch with the local chapter of the Architects' Association and clear the matter up so that this erroneous impression may be permanently removed.

How I Increased My Sales 100 Per Cent.

By a Successful Retailer

It's a wonder the manufacturer and jobber in electrical supplies don't take a more personal interest in the retailer and his methods. Isn't it plain that if the retailing end is weak, the demand for goods from the manufacturer and jobber is just so much less and their profits are correspondingly low. Somebody most assuredly has got to come to the aid of the unskilled retailer—show him how to be a merchant—or years will go by without any appreciable improvement in the situation.

Now, the obstacles that stand between the contractor-dealer and success are twofold. First, he doesn't know how to merchandise and, second, he hasn't the necessary capital. This latter applies, at least, to a very large number for we retailers are now coming to realize that we can't carry on a successful selling campaign on good intentions alone. We need a first-class location, a fairly comprehensive stock and, finally, money enough to come and go on to make it possible to sell on the installment plan.

Speaking personally, I have had wonderful results since I started to sell appliances on the monthly payment basis and am convinced that this is the right course for any dealer to pursue. We have got to get electrical appliances into the homes of many a man who has not the ready money to pay for them spot cash—so we dealers must carry him along for a while. Of course, he pays a little more for the article so that we get interest on our money. I have specialized on ten payments, though that seems to be longer than the average, but six payments for a washing machine, say, calls for fairly big monthly installments. Besides, ten is an easy number to calculate with and your customer is not led into a maze of figures which take his mind off the main object—the appliance.

A few years ago the idea of buying anything on the installment plan was much less in favor than it is today. How many Victory Bonds would the Dominion Government have sold, however, if they had demanded cash payments. Come to think of it, how many of the commercial enterprises which form the basis of our industrial activity and stability could continue to carry-on if the banks withdrew their support. The whole fabric of our commercial life is woven with "credit" and we need not fear that we are advocating a policy that is fundamentally unsound when we offer to sell appliances on an installment basis.

I now sell any appliance, of whatever, value, in this way, with 5 per cent. off for cash, though very few of my customers take the cash option. My sales have not only doubled but I believe I can trace to this new policy an increase to four times my turnover of a year ago.

Montreal Armature Works

The officers of the Montreal Armature Works, Ltd., electrical engineers and contractors, Montreal, are all technical men. Mr. S. D. Sweetnam, B.Sc., the president and managing-director, is a graduate in electrical engineering of Finsbury Technical College, London, England, and McGill University, Montreal. After graduating from McGill he joined the test department of Allis-Chalmers Bullock, and was later erecting engineer for the company. He started in business in 1914, in the firm of Giddings & Sweetnam, which was dissolved in 1917, after which he established the Eastern Electric Co.; this was continued until May 1st of this year, when the Montreal Armature Works, Ltd., was formed.

Mr. N. C. Mills, C.E., E.E., A.I.E.E., the vice-president, is a graduate of Harvard University in civil and electrical engineering. After graduating, Mr. Mills was engaged on survey work in Newfoundland & Labrador, afterwards joining the General Electric Company of Schenectady. For several years he was chief induction motor designer for the Canadian General Electric Co., Peterborough. When the United States entered the war he volunteered for service and was assigned to the engineering officers' training corps and was afterwards discharged on account of his health.

Mr. P. J. Dolan, director and shop superintendent, obtained his theoretical training at the Manchester School of Technology. He served a four-years' apprenticeship at the shops of the Industrial Engineering Co., Hyde, Cheshire, Eng., and afterwards worked in the winding departments of the British Westinghouse; General Electric Co., of Witton; Bruce, Peebles & Co.; Vickers, Ltd.; and the repair shops of the London Electric Railways and White Jacoby, London. After coming to Canada Mr. Dolan worked four years in the winding department of the Canadian General Electric Co., Peterborough, and for three years was the electrical superintendent of the Wayagamack Pulp & Paper Co., Three Rivers. He joined the Royal Air Force, Mechanical Section, in 1917, and on his discharge this year joined the Eastern Electric Co.

Circular on Electrical Precipitation

A circular describing the Westinghouse achievements in the field of electrical precipitation has just been issued. The process applies to copper, lead or zinc smelters, blast furnaces, chemical, acid and cement plants for the recovery of valuable material otherwise wasted. Water can be precipitated from oil, dust removed from ventilating systems, etc. It is also applicable to operations such as round houses which by their smoke or fumes are a nuisance to the surrounding territory. The necessary apparatus for the precipitation process such as motor-generators, transformers, rectifiers, motors, switchboard and accessories are shown installed, and are described in detail in this circular. While there are several mechanical and chemical methods for collecting or suppressing dust in furnace and kiln operation, they are in general limited in application by conditions of temperature, acid, and similar qualities of the product to be handled. Electrical precipitation has few limitations of this sort and is generally applicable for collecting suspended solid and liquid particles of every description, whether acid, alkaline, or from gases of widely varying temperature.

Bear in mind that in Canada, as in the United States, you have not reached 5 per cent. of your potential market. You still have 95 per cent. of the road to go—a road of commercialism, popularization; intensive selling.—W. L. Goodwin

Uni-Lectric Lighting Plant

The illustration herewith represents the Uni-Lectric lighting outfit, for which the Masco Company, Limited, are distributors in the province of Ontario. This equipment embodies features that hitherto have not been found in many electric lighting plants. It is built in one capacity, 1,000 watts, for 110 volts, and is of both the hand starting and the electric starting type. In the hand starting type the engine is cranked in the same manner as an automobile, but in the electric starting type there is provided a standard automobile type of starting equipment, including a 6 volt battery, starting motor and Bendix drive. A solenoid switch actuated from the 6 volt storage battery by pressing an ordinary push button, which may be located at a convenient point or points, throws the starting motor across the storage battery and cranks the outfit. Releasing the pressure on the push button immediately opens the switch when the unit is started. A second push button may be installed to short circuit the magneto and stop the equipment. These push buttons are usually arranged on a 3-wire system with

Masco Co., Toronto, are agents for this farm lighting outfit

a common return, and on account of the low voltage may be wired the same way as bells or annunciators. In this way as many starting and stopping stations may be installed as the customer desires, it being only necessary to carry the three wires from each station.

The engine on these equipments is a single cylinder rotating sleeve valve type. It is equipped with a high tension magneto and a solenoid control butterfly valve so that the voltage is automatically regulated and it is unnecessary to discharge through storage batteries in order that the voltage regulation may be obtained. The absence of storage batteries simplifies the equipment and there is no loss of energy through the charging of such battery. In addition to this feature the 110 volt generator increases the range of service and decreases the cost of wiring. It is also possible to use standard code wiring throughout and the ordinary heating appliances, small motors, etc., as sold for central station service, may be used on the equipment. The highest grade of materials has been used and the outfit has been so designed as to present a most compact and presentable unit. It is also possible to readily gain access to any part of the equipment for examination.

Factory tests have shown, under 200 watt load, nine hours run per gallon of gasoline; under 500 watt load, 5½ hours run per gallon, but this is largely dependent on the grade of gasoline. The gasoline consumption increases very slightly with increase of load from ½ load up to full load.

Locomotive Type Ampere Hour Meter

The experience of the past few years in the operation of storage battery trucks, tractors and battery mine locomotives has clearly demonstrated that the chief problem in the operation of these devices is the problem of the storage battery. Accordingly, the ampere-hour meter, which is the only device that automatically gives a true indication of the state of charge of the storage battery at all times and automatically terminates the charge at the proper time, is of special importance in this connection. A new locomotive type ampere-hour meter has just been designed by the Sangamo Electric Company in order to meet the severe requirements as to overload and vibration experienced in this particular service.

The ampere-hour meter when installed permanently in the storage battery circuit on the truck, tractor or locomotive, registers every ampere-hour which the battery discharges in driving the vehicle, and since the total battery capacity is indicated by the red "Empty" hand on the meter, the black hand indicates the remaining capacity left in the battery. The operator then knows at all times how much farther he can run

Wiring diagram of ampere-hour meter

the truck. When the battery is later put on charge the ampere-hour meter registers as the charge proceeds, operating in a direction reverse from that of discharge. When battery has been fully charged the meter will register zero and make contact within the meter which trips circuit breaker in the charging circuit.

No battery is 100 per cent. efficient. More charge must be given than was taken out on the previous discharge, so there must be a certain amount of excess charge each time the bat-

Sangamo ampere-hour meter

tery is charged. This feature is automatically provided for in this meter by means of a variable resistor device which causes the meter to run slower by any desired percentage on charge than on discharge for equal current flow. This automatically

provides that the battery will be given any desired percentage of overcharge, for, by the time the meter indicating hand gets back to the full charge position, all of the previous discharge plus a certain percentage overcharge (depending upon the setting of the variable resistor element) will have been put back into the storage battery. This feature is entirely automatic, and once the resistor has been set at the desired percentage of overcharge, no further attention need be given the device.

This locomotive type meter which has been especially designed to meet the severe requirements of mine locomotive and industrial truck service embodies several distinct improvements over previous Sangamo ampere-hour meters.

1. Overload capacity increased.—Locomotive type meter will carry 300 per cent. load continuously and 500 per cent. load for 3 minute periods without undue heating of any parts.

2. Meter made dust and moisture proof by means of improving binding posts, terminals and soft rubber gasket in case.

3. New type contact at zero.—This is mounted entirely back of the dial and operates on cam principle instead of lever as formerly, thereby reducing drag on meter and increasing reliability of the action of the contact.

4. Modified motor element.—Special treatment is given to both the armature disc and armature box interior which has reduced the formation of mercury dross to about $\frac{1}{4}$ of that formerly experienced. This will probably improve the meter operation very greatly and eliminate trouble due to meters being slow on account of dross.

5. New type variable resistor element which is approximately eight times as effective as the resistor element formerly used. This insures greater reliability of operation and increases the range of adjustment so as to provide a maximum of 50 per cent. overcharge where desired.

6. Reset made dust proof.

7. Lock washers throughout and special rugged construction combined with mercury flotation of the rotating element, make the locomotive type meter immune from vibration and loads.

Standby for Pumping Plants

The illustration herewith shows the installation recently made at St. Johns, P.Q., to the designs and specifications of Ouimet & Lasage, civil engineers, Montreal, for a standby auxiliary in the pump house. The prime mover is a "Sterling" 200 h.p. gasoline engine driving a Kingsford 2-stage 3,000,000 gal. capacity turbine pump, suction 12 in., discharge

Gasoline-engine driven pump at St. Johns, P.Q.

10 inches, total head, 235 feet. The units are direct connected and have a speed of 1,400 revolutions per minute. The engine was supplied by the Pyke Motor and Yacht Company of Montreal. The pump was supplied and installed by the New York Jewell Filtration Company, New Birks Building, Montreal. The "Sterling" engine is finding a wide field in Canada for stand-by purposes, the insurance companies' regulations demanding, in many cases, that an auxiliary supply of power must be available in case of failure in the electric service.

Moving Tonnage in Large Units

The ability to increase track capacity for the rapid expedition of heavy freight trains is fast becoming a difficult problem, owing to the tremendous increase in train ton-

250-ton locomotive

nages to be moved as a unit. In other words, the problem before many steam railroad operators is how to increase the physical capacity of a certain heavy tonnage division without prohibitive expense. At the same time, after such an expenditure in correcting alignment, grade reductions and other operating difficulties, there still remains the problem of operation, namely hauling without delay the tonnage offered for transit. The introduction of the large 250-ton locomotive of the Pennsylvania Railroad recently exhibited at the Master Mechanics' and Master Car Builders' Convention held at Atlantic City, is an advance in the possibility of moving heavy tonnage in large units over steep grades. Here we have maximum accelerating horsepower of 7,600, with a sustained horsepower capacity of 4,800 for one hour. With two of these engines a 6,300-ton train can be handled up long grades at constant speed; as, for instance, on a 25-mile 1 per cent. grade, such a train could be moved at 20.6 miles per hour. Thus there exists equipment for hauling traffic in larger units and with the rapid movement of such large quantities of freight the division rapidly becomes cleared, ready to handle additional tonnage. This locomotive was designed under the general direction of Mr. J. T. Wallis, general superintendent of motive power, Pennsylvania Railroad, together with Mr. B. G. Lamme, chief engineer Westinghouse Electric & Manufacturing Co.

The great problem of the electrical industry of the future is the commercial problem.—W. L. Goodwin.

Commercial Lighting Units

Scores of business men are to-day becoming more than ever interested in better lighting as a means of increasing efficiency, and there is a good field in this direction for dealers who are interested in going after the business. The large majority of stores, offices, schools, churches, assembly halls, display rooms, and so on, all have old-time lighting fixtures—principally because they have not been shown the advantages of the new, modern lighting units. The illustration

"Clearlite" No. 2609

herewith shows the "Clearlite," No. 2609, manufactured by the Tallman Brass & Metal Company, Hamilton, Ont. This fixture is scientifically constructed and comes in several styles. It is particularly suitable for commercial lighting of all kinds.

New Publications

"We Welcome Fair Competition," is the title of a circular just issued by the Portable Machinery Co., Passaic, N.J., manufacturers of the Scoop Conveyor. It briefly describes how one concern has copied and is trying to market an imitation of the Scoop Conveyor. As there is suit now pending for infringement of rights, the circular warns possible customers of portable conveyors against purchasing the imitation.

Mr. Strickland in Brantford

Mr. H. F. Strickland, chief electrical inspector for the Hydro-Electric Power Commission of Ontario, was in Brantford recently looking over that inspection district. While there he attended a meeting of the Telephone City Electrical Club and a good many points in connection with the rules and regulations, which were not clearly understood, were discussed and expained. His visit will tend toward better relations between the inspector and the contractors. Mr. Strickland's idea of periodical visits to each district under his supervision is a good one, and is bound to be productive of splendid results to the electrical business and will greatly assist the contractor as well as the inspection department.

The Marchand Electrical Co.

Mr. P. E. Marchand, electrical engineer and contractor, for the past twenty-one years senior member of the firm of Marchand and Donnelly, of Ottawa, is severing his connection with Mr. W. L. Donnelly on August 1st, and going into business with his sons, under the name of Marchand Electrical Co. They will carry on the business of electrical engineering, contracting and commission agents.

Personal

Lieut.-Col. John Wise, D.S.O., M.C., who recently returned from overseas, was, at the outbreak of war, a motor-man in Halifax. He enlisted as a private.

Mr. V. K. Stalford, former District Electrical Inspector Hamilton District Office of the Electrical Inspection Department of the Hydro-Electric Power Commission of Ontario, has resigned, and will open an office in Hamilton as a consulting engineer. Mr. Stalford is very well and favorably known in the industry, and his friends, who are legion, will wish him every success in his new venture.

Mr. R. J. Hillier, a well-known figure in the electrical industry, has been appointed manager of the electrical department of the International Machinery and Supply Company, Limited, 371 St. James Street, Montreal. Mr. Hillier was formerly a very active figure in the Canadian Electrical Association. He started in with the old Royal Electric Company in 1887, following which experience he spent some years with the Canadian General Electric Company and with John Forman. Later he transferred his activities to the Engineering Equipment and Supply Company. Mr. Hillier is widely and favorably known and his thoroughly intimate knowledge of the jobbing trade will be a fine asset to the company with whom he is now associated.

Mr. Thomas F. Kelly, formerly with the Dominion Power & Transmission Company of Hamilton, but since February 1, 1913, with the Dayton Power & Light Company, has returned to Canadian soil as Canadian Sales Manager of the Hoover Suction Sweeper Company. The Canadian headquarters of the Hoover Company, until recently at Windsor, is being moved to Hamilton, where they are building a new plant, and where Mr. Kelly will have his office. Sweepers will be manufactured for distribution in Canada and probably throughout the British Empire. Judging by the regret

Mr. Thomas F. Kelly

expressed by Mr. Kelly's friends in Dayton, he was a great success there, just as he had been with the Dominion Power & Transmission Company. We trust that success will stay with him in his new position and that the sales of the company he represents will continue to increase under his guiding hand.

Volume 1 of the eleventh annual report of the Hydro-electric Power Commission of Ontario, has just been printed. This is for the fiscal year ending October 31st, 1918, and contains information in connection with (1) Legal Proceedings; (2) Transmission Systems; (3) Operation of the Systems; (4) Construction Work of the Commission and (5) General Activities of the Commission.

PHILLIPS' ARMOURED CABLES

A detailed cross-sectional view of a large, circular electrical cable. The cable has a thick, dark outer jacket. Inside, there are three distinct circular conductors arranged in a triangular pattern. Each conductor is filled with a cluster of small, light-colored spheres, likely representing the strands of the conductor. The conductors are separated by a thin layer of insulation, and the entire assembly is surrounded by a thick, dark, textured layer, which is the double steel tape armouring mentioned in the text.

Current News and Notes

Brantford, Ont.

The Electric Tin Products Company, recently granted a Dominion charter, will erect a plant in Brantford, Ont.

Chatham, Ont.

The Chatham, Wallaceburg and Lake Erie Railway have completed arrangements to operate with Hydro power and the change-over will be made within the next few weeks.

Erieau, Ont.

The ratepayers of Erieau, Ont., have circulated a petition to have the Hydro line extended from Blenheim, Ont. The power could be used to advantage in operating the large coal docks, as well as by a number of summer residents.

Guelph, Ont.

An agreement has been prepared and will shortly be voted on by ratepayers authorizing the Grand River Railway Company taking over the control and management of the Guelph Radial Railway Company. A number of changes are contemplated, including track repairs, new one-man cars and more rapid service.

Halifax, N.S.

The Board of Public Utilities has made an order authorizing an issue of \$1,000,000 seven per cent. gold notes of the Nova Scotia Tramways Company, the funds to be used for track renewals, additional cars, equipment for power stations and extensions to lines. Much of the work will be carried out this year.

Hamilton, Ont.

Messrs. Hunter and Strome, formerly with Snyder Bros., electrical contractors, fixtures and supplies, King William Street, Hamilton, have recently purchased the business of Ernest Wark, electrical contractor-dealer, 167 King Street East, Hamilton.

Hastings, Ont.

The Hydro-electric Power Commission of Ontario, it is stated, will proceed with the erection of the 44,000 volt transmission line from Healey Falls to Peterboro this season, which will make it possible for Havelock, Norwood and Hastings to have Hydro service.

Kenogami, Que.

It is reported that a power plant will be constructed on the Shipshaw River, Kenogami, Quebec, by Price Brothers Company, Ltd. The estimated power available is 15,000 h.p.

Montreal, Que.

Earnings of the Southern Canada Power Company for June, 1919, were \$48,961, an increase of \$9,012 over the same month last year. Operating expenses were \$25,551, an increase of \$2,801.

A. A. Giddings & Co., Montreal, have been awarded the contract for the electrical fixtures and lamps for the Hunter Building, Ottawa. These are of special design.

The strike of Montreal wiremen has petered out. Three or four firms with rush orders conceded the union rates, one or two others made compromises, the majority have obtained all the labor they want on the old terms, and many strikers are now out of jobs.

The Montreal Light, Heat & Power Consolidated, has reduced the price of electric light. The rate is 6c per kw.h., and the discount has been increased from 16-2/3 per cent. to 20 per cent. This makes the net 4.80c per kw.h., which becomes operative in October. At the same time the directors increased the dividend rate to 5 per cent.

Mr. William T. Scott, for over thirty years connected with the Bell Telephone Co., Montreal, died on July 10 at Napanee, Ont. Mr. Scott, who retired in 1913, for many years held the position of special agent for the company in Montreal.

St. Boniface, Man.

An automatic telephone system is being installed in St. Boniface, Man., where there are about 900 lines.

St. John, N. B.

The New Brunswick Power Co., St. John, recently offered a place on the directorate to a member of the union of the company's employees. The latter have decided not to accept the offer for the present.

St. Thomas, Ont.

T. W. Lester, St. Thomas, Ont., has changed his store name from The Electric Supply Company to Lester Electric.

Toronto, Ont.

The Electric Materials and Products Company have been granted an Ontario charter. The capital stock is \$50,000; head office, Toronto.

Members of the Toronto City Council recently inspected the Chippawa development at Niagara Falls.

Winnipeg, Man.

The route being followed for the transmission line from Winnipeg to Portage la Prairie, Man., by the provincial government, is approximately 59 miles in length and will cost about \$215,000. Power will be delivered from the Scotland Avenue sub-station of the Winnipeg power plant at 12,000 volts; stepped up to 66,000 volts for transmission and stepped down to 22,000 at Portage la Prairie. A further expenditure of about \$60,000 will be entailed by the construction of the sub-station and equipment at Portage la Prairie and changes to the Winnipeg sub-station.

Mr. Geo. K. McDougall, Drummond Building, Montreal, announces he has taken into partnership Major E. Raymond Pease, D.S.O. The name of the new firm will be McDougall & Pease, consulting engineers, specializing in industrial applications of electricity, illuminating engineering, electric power stations, high voltage power transmission etc.

The Armstrong Cork and Insulation Company, Pittsburgh, Pa., are distributing two valuable little folders entitled, "Nonpareil Corkboard Insulation for Cold Storage Rooms and Freezing Tanks" and "Saving 63% of the Drinking Water Expense." Supplied on request to the company.

The British Aluminium Co. are distributing a little booklet, entitled "The Casting of Aluminium," including a quantity of information, under the following headings: Alloys; Mixing Alloys; Moulding; Melting. It may be obtained upon application to the Company at 265 Adelaide Street West, Toronto.

The Ward-Leonard Company have issued an interesting little folder entitled "The 15 Year Club," showing photographs of employees who have been with that company for 15 years.

The Wagner Electric Manufacturing Company, of Saint Louis, announces the removal of its Philadelphia office, service station and warehouse to 1632-34 Sansom Street.

Sterling Emergency POWER

Instantaneous, efficient, dependable, for centrifugal pump and electric generator drives. 10 to 300 Horse Power, 2, 4, 6 and 8 cylinder gasoline engines, 200 to 1400 R.P.M.

Sterling Model FS, 4 cylinder engine, 100 H.P. at 1400 R.P.M. direct connected to Eric Pump Co.'s 3-stage type M.S. centrifugal fire pump for U. S. Navy.

Publisher's Notice

Advertisements under "Situation Wanted" or "Situation Vacant" are charged at two cents a word per insertion, minimum charge 50 cents.

Advertisements for tenders, equipment, wanted or for sale, etc., or miscellaneous, are charged at \$2.50 per inch.

All advertisements must be in the publisher's hands by the 10th or 23rd of the month to insure insertion in the subsequent issue.

WANTED TO PURCHASE

Wanted to purchase in quantity 2 H.P., 3 H.P. and 5 H.P. Motors, 550 Volts, 3 Phase, 60 Cycles. Write Box 983, Electrical News, Toronto. 14 15

FOR SALE

One Type N Montague Mailing Machine, 110 V., 25 cycle, used two years. What offers?

HYDRO-ELECTRIC SYSTEM,
120 Welling Ave.,
Niagara Falls, Ont.

15

The Fourteen Points of "Quality Electrical Work"

1. Thoughtful lay-out of the job, explaining to the customer what he should have.
2. Quality material—remembering that quality is usually indicated by price.
3. Conscientious workmanship, prefer-

ably on time and material basis—where the customer pays only for what he gets.

4. Oversize wiring.
5. Plenty of outlets for portable lamps.
6. Plenty of outlets for appliances.
7. One standardized form of outlet throughout the house, so that all plugs and cords will be interchangeable.
8. A separate circuit for heating and motor appliances.
9. Two-way switches and remote-control switches where indicated by customer's convenience.
10. Regard for principles of good taste and good lighting in locating all permanent fixtures.
11. Consideration of customer's convenience in locating all switches, outlets, etc.
12. Meter board located so that meter can be read without entering house.
13. Provision for future extension to wiring.
14. A fair price to permit good work.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

Resurface Commutators While in Service

The Ideal Resurfacer will keep your commutators in perfect condition. You can forever eliminate the trouble and expense of shutting down equipment to turn down commutators on a lathe. They can be kept in perfect condition by the occasional use of the Ideal Resurfacer while running under full load.

IDEAL COMMUTATOR RESURFACER

is a manufactured abrasive block that will quickly cut down high mica ridges and high bars, smooth out grooves and low spots on your commutators. It is non-metallic and non-copper collecting. Not a natural stone, sometimes hard and sometimes soft, that clogs with copper dust, but a specially prepared product of uniform density and cutting quality throughout.

FOR "D-C" OR "A-C" EQUIPMENT

The Ideal is equally effective on both "D-C" and "A-C" equipment—it will keep commutators and collector rings smooth, free from sparking and save in wear and tear upon carbon brushes. It will pay for itself many times through increased efficiency of your equipment and in time and labor saved, keeping commutators and collector rings in A-1 condition.

SEND THE COUPON

In order that you may convince yourself of the value of the Ideal we want you to try it out on your own equipment. If you like it send us a check—if not return it at our expense—the trial will not have cost you a cent. That is fair—fill out the coupon now while the matter is in mind.

How Our Advice

Doubled Sodering Output

at it
since
'93

A large manufacturer of small motors asked our service department to help speed up the operation of soldering lead wires into commutator bars.

It took us only a few minutes to suggest changes in flux and in soldering tools that will ultimately double the output.

Let us help you solve your problems.
Be very specific when writing.

Bissett & Webb

126 Lombard, Winnipeg, Man., Canada

"Clearlite" No. 2609

"Clearlite" fixtures are made for almost every purpose and to meet all conditions.

Because of the high quality glass they produce a soft diffused light, without glare. The especially designed white enameled reflector assures the utmost in lighting efficiency, downward, where it's wanted.

Write for descriptive folder.

The Amelite

Store Lighting

*The Demand for efficiency
is fulfilled in the Amelite*

Progress in effective store lighting has reached a worthy achievement in the Amelite.

It brings to you profit, quick sales and good will. For wherever installed the Amelite has created a new standard—it combines efficiency, moderate cost, and most appropriate design.

If you sell lighting glassware or fixtures of any kind, you need the Amelite. It gives a new impetus to your sales; it opens a market not so readily reached in any other way.

BRADSTREET'S

Offices Throughout the Civilized
World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

"Just What I Want"

This is exactly what you, or any one else, will say after having bothered around with loose extension cords.

The Automatic Extension Reel

for Electric Lamps

Obviates the necessity of dragging your cord over the floor, thus wearing out insulation and breaking sockets, guards, etc. Takes your light just where you want it, locks at any point, and automatically rewinds your cord when you are through with light. Contains 25 feet of approved reinforced weatherproof cord.

Approved by the Underwriters, and endorsed by fire and electrical bureaus everywhere. Fully protected by two basic patents and more pending. Write for further particulars and prices.

The Cincinnati Specialty Mfg. Co.
Inc.

1907-19 Powers St., West, Cincinnati, Ohio

Uni-Lectric Lighting Plants

Farm Lighting Standardized 110 volts Direct Current.

Capacity—1000 watts.

Construction — Best workmanship, simple, accessible, compact.

Regulation—Excellent.

Types—Self Starting (push button control) or Hand Crank.

Advantages — No batteries needed — save charging loss—uses standard code wiring, lamps, motors, and appliances—transmits power over larger areas.

ECONOMY renewable FUSES

Owe their enviable prestige to their consistent efficiency in performance. They are the trusty guardians of millions of circuits for thousands of users who have learned from experience that they invariably measure up to the highest standards by which fuses may be judged.

As compared with the use of one-time fuses, they cut annual fuse maintenance costs 80% because an inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

Economy Fuses make friends for the contractor who writes them into specifications and the dealer who recommends them.

WALGER CONNECTORS

Solderless Connection

Patented Canada 1917.
Patent Pending U. S.

Walger 2-Way Connector

For connecting in chandeliers and canopies, for lengthening extension wires, for exchanging fixtures, for making connections in cramped places. The safest, simplest, the most convenient method to use

$\frac{1}{5}$ the time
 $\frac{1}{2}$ the cost

No solder, no blow torch—connecting time and trouble reduced—by the simple, compact, inexpensive WALGER CONNECTOR.

Every Walger installed insures a perfect connection—quick, easy, permanent. It provides absolute insulation.

You eliminate all muss on the job when you use WALGERS. No drops of solder, burnt matches nor finger to mar your good workmanship.

WALGERS make the connection in one-fifth the time at one-half the cost. Use WALGERS on your next job.

Passed by the National Board of Fire Underwriters and the Hydro Electric Power Commission for No. 12 wire and smaller.

Ask Your Jobber

Walger 3-Way Connector

Use it to tap feed wires in outlet boxes, in Condulets, or on knob and cleat work. Make a secure connection, absolutely insulated. Makes work quick, easy, smooth.

Walger Connector Company

Sales Agent: C. JACKSON, 22 College Street, TORONTO, ONT.

GREATER BUYING POWER

That is what the trade paper represents to the man who is a regular and careful reader of it.

In its editorial columns he finds useful ideas that help him in his business—helps and hints that smooth out many of the rough spots—plans the other fellow has tried and found successful.

The advertising pages are also a source of valuable information. Here he learns what the manufacturer has to offer—how those goods are made—the materials that enter into their manufacture—when salesmen are on the road—special opportunities, etc.

He keeps thoroughly posted on the market, because the trade paper is in close touch with the situation and gives him accurate knowledge of conditions—when and what to buy.

Read your trade paper thoroughly each issue and make a reference file of it. You will often have occasion to refer to it.

**This SOLENOID SWITCH has been adopted
by the Hydro Electric Commission**

**They use it for
STREET LIGHTING**

Now the fact that it is used by the Hydro-Electric Commission is proof that it is all we claim for it. It certainly is not an experiment, by the fact that it is giving efficient service in many towns throughout Ontario, as well as the other provinces.

No springs, swivels or other complicated mechanisms to give trouble. They close magnetically and are opened by gravity assisted by the tension of the laminated copper contact. All arcing is taken up on the carbons.

Increase the efficiency of your system and decrease the cost of installation by using our Type 17 H.E.P. Solenoid Switches, which are suitable for any frequency on multiple circuit or D.C. Series circuit.

HAVE you considered the G & W POTHEAD IDEA in your plans for improvements and expansion of your distribution system ?

If not you are neglecting something that will save you money—money in equipment and installation costs—money which might be lost from service interruptions. And what is of even greater importance, you are neglecting features which will provide a maximum of flexibility in your distribution system, making load shifting, future extensions, or quick changeovers easily accomplished if the occasion demands—and without cable cutting or "temporary work."

That is in general what the G & W Distribution Idea has accomplished for some of the largest Central Stations in the country—and it can do the same for you.

The Disconnecting Pothead and its various outgrowths are responsible for the soundness and reliability of the G & W Distribution Idea. In addition to being a dependable, moisture proof cable seal, the Disconnecting Pot Head is a simple and serviceable sectionalizer which does away with the need of a switch—all for the price of an ordinary cable seal. This feature in itself is worthy of consideration—not to speak of many other convincing advantages of the G & W Idea.

Have you received new Catalog No. 10? Contains Valuable illustrations and drawings for every Central Station Engineer

Adjusto-Lite

A FARBERWARE PRODUCT

TRADE  MARK

It Clamps Everywhere

Patented in U. S. and Canada

Every Home, Office and Store in Your Town Needs Adjusto-Lite

AND you can sell them Adjusto-Lite, because it fills the need for a strong clear light in many places where the regular lighting is insufficient.

Simply show your customers how Adjusto-Lite clamps everywhere—to desk, shelf, counter, bed, mirror, etc. How it throws a clear pleasant light just where light is needed—and they will buy Adjusto-Lite because they need it, and will pay the reasonable price.

Many of your customers will come to you for Adjusto-Lite because they read about it in the Saturday Evening Post and other big publications in which our strong advertising appears.

CARRIES A GOOD PROFIT FOR YOU

And it is a quality product. Made of solid brass, in brush brass, statuary bronze or nickel finish. Compact, weighs little, easily carried about. Sold complete with 8-foot silk cord and Bryant push-button socket. Guaranteed five years. Individually packed in display cartons for easy selling.

PRICES TO DEALERS:

In quantities of 3 dozen or more: \$3.00 for brass, \$3.25 for bronze or nickel.

In lesser quantities: \$3.25 for brass, \$3.50 for bronze or nickel.

Terms 2/10, 30 days net, f.o.b. New York.

Send for assortment of six lamps. Display them in use on desk or table. **THEY'LL SELL!** If not as represented, return at our expense

A Comparison

Sherardizing Steel & Creosoting Wood

The Purchasing Agent for one of the largest Hydro-Electric Power Companies, upon having the Sherardizing Process thoroughly explained to him, remarked:

"Then Sherardizing, as a method of protecting steel, is like creosoting for protecting wood."

He has since insisted upon the delivery of **SHERARDUCT** on all conduit orders.

The two processes are markedly similar, both in treatment and results attained. **SHERARDUCT** is the only Sherardized Rigid Steel Conduit. Both interior and exterior surfaces are Sherardized and further protected by coatings of a clear acid- and alkali-proof enamel, baked on. Has the combined advantages of zinc and enamel protection. Double value for one price. We can't tell you all about it here; write for complete information.

*British Material
Canadian Workmanship*

The C. & H. Meters have long held the premier position for their accuracy, simplicity and scientifically correct construction.

Besides being absolutely the best instruments you can install for reliability, they represent a combination of Canadian and British production. With the war ended many of the obstacles of obtaining raw material from Britain have been removed, and we are now in a position to make old time prompt delivery.

A Time and Labor Saving Screw for Electrical Contractors

Robertson *Patented* **Socket Head** **Wood Screw**

In these days of high costs of labor and material, you want to save wherever you can. The Robertson Socket Head Wood Screws will save time, money and material. They are easy to drive—all you have to do is place the screw on the driver—it sticks there, enabling you to drive at arm's length if you wish. Indispensable for use in hard-to-get-at places, such as between joists, under floors or between narrow openings.

Let us prove our statements by sending a few samples and our prices.

We supply bits to suit any ratchet, also drivers in all suitable styles free with first order.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Accurate—Rugged—Inexpensive

In factory or field, the Type S set will quickly and accurately measure resistance or locate faults. It will withstand, without detriment to its electrical qualities, the knocks which such a set is bound to get. It is of the Dial Decade Type, and therefore simple to operate. Excellent design plus quantity production enables a low price without sacrificing accuracy. ratio coils 1/20 per cent, rheostat coils 1/10 per cent guaranteed. The removable suspended coil galvanometer deflects a millimeter per microampere. This combination—accuracy of adjustment of coils, sensitivity of indicator, ruggedness, inexpensiveness—is found only in the Type S set.

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

Good Bonding Starts a Series of Paying Results

When the return circuit is well bonded the most frequent cause of low voltage is removed. And when the voltage is up to normal several good things happen.

Motors pull the cars along on time.

Motors keep cool so that most burnt out armatures are avoided.

Juice stays in the track and power costs are lowered—overloaded equipment is relieved.

Car lights and headlights are bright.

Good bonding pays.

O-B Bonds are good bonds.

Send for New Book, "The Return Circuit." It goes to the heart of its subject.

Both Appreciate the Advantages of R & M Motor Equipment

The superintendent of the factory which makes electric-driven devices likes the R & M Motor because the motors supplied him are perfectly adapted to his product. His manufacturing problems are simplified and the efficiency of his product is increased.

And the sales manager likes the R & M Motor in the product he has to sell because R & M Reliability holds business for him and reduces selling expense. He finds, too, that the name Robbins & Myers used in connection with his device creates added prestige for his goods. For many years of dominant advertising in the

leading general magazines has made R & M Quality something which is generally known everywhere.

The R & M Motor is the one motor everyone knows about. Every prospective user of a motor driven device, whether for home, office, store or factory, recognizes the R & M Motor as the best insurance of reliable service from the machine.

From both standpoints—service reliability and saleability—manufacturers find advantages with R & M Motors. And for the same reasons, dealers find maximum satisfaction and profit in the sale of devices so equipped.

No. 16

Ontario Power Company's Plant Reaches Ultimate Development

This issue contains a detailed description of the latest and final addition to the Ontario Power Company's plant at Niagara Falls, now owned and operated by the Hydro-electric Power Commission of Ontario. It consists of an installation of two units of 15,000 kv.a. each and necessitated the installation of a third pipe line. Such an expense would scarcely have been justifiable in view of the more economical development now proceeding at Queenston, had the requirements of war industries not reduced the supply of power available to a figure considerably less than the demand. However, as a piece of engineering work, it is none the less interesting because it may prove a more or less temporary necessity. As the demand for power increases the Hydro Commission will probably find it necessary to utilize the water that now passes through the Ontario Power Company's turbines, at the more economical plant now building at Queenston, where the head is more than twice as great. In the meantime, this plant is one of the most up-to-date and efficient on the continent.

Every phase of labor and organization required by the exigencies of modern warfare are shown in the Canadian War Memorials paintings to be exhibited at the Canadian National Exhibition this year.

Among others, the "Hell of Death" that faced the Canadians at the second battle of Ypres, when they were set against the first German gas attack, is vividly portrayed.

City of Guelph Accepts Its Moral Obligation to Support Hydro-Radials

The city of Guelph very decidedly defeated the by-law to sell its local electric railway system to a private corporation. The Grand River Railway Company not only offered a fair value for the system, but also promised extensions. The city decided, however, that it would be serving its best interests to stand by Sir Adam Beck and Hydro-radials, and Sir Adam has given his promise that work on these radials shall proceed without further delay.

The vote does not necessarily mean that Guelph was dissatisfied with the offer of the private company, but rather, no doubt, that they were determined to stand by the other municipalities that had committed themselves to the municipal hydro radial scheme. The only possible way to make the Beck scheme a success is for everybody to stand back of it. A single defection can cause untold trouble. In voting as they did Guelph was unquestionably following the honorable course. If all the municipalities speak in the same decided way it should also prove the wisest course.

Prince of Wales as a Soldier

Many charming little stories, demonstrating his great human and soldierly qualities, are being told about the Prince of Wales, who will open the Canadian National Exhibition on Monday, August 25th. The Canadian boys overseas had plenty of opportunity to observe his actions and declare that he seemed to love danger, and at times his conduct bordered on the reckless.

This side of his character is well illustrated by the following extract from Ian Hay's book, the First Hundred Thousand.

"Blaikie lit his pipe—it was almost broad daylight now—and considered.

"Yes," he agreed. "Perhaps. Still, my son, I can't say I have ever noticed staff officers crowding into the trenches (as they have a perfect right to do) at four o'clock in the morning. And I can't say I altogether blame them. In fact, if ever I do meet one performing such a feat, I shall say: 'There goes a sahib—and a soldier,' and I shall take off my hat to him."

"Well, get ready now," said Bobby. "Look."

"They were still standing at the trench junction. Two figures in the uniform of the staff were visible in Orchard Trench, working their way down from the apex, picking their steps amid the tumbled sandbags, and stooping low to avoid gaps in the ruined parapet. The sun was just rising behind the German trenches. One of the officers was burly and middle-aged; he did not appear to enjoy bending double. His companion was slight, fair-haired, and looked incredibly young. Once or twice he glanced over his shoulder, and smiled encouragingly at his senior.

"The pair emerged through the archway into the main trench, and straightened their backs with obvious relief. The younger officer—he was a lieutenant—noticed Captain Blaikie, saluted him gravely, and turned to follow his companion.

"Captain Blaikie did not take his hat off, as he had promised. Instead he stood suddenly to attention, and saluted in return, keeping his hand uplifted until the slim, childish figure had disappeared round the corner of a traverse.

"It was the Prince of Wales."

Mr. Higman Takes Issue With Report of Meter Committee

Ottawa, July 31st, 1919.

Editor, Electrical News:

Referring to the report of the Meter Committee of the Canadian Electrical Association published in your July issue, I would ask permission to correct some of the "presumptions" and mis-statements of the Committee.

For instance, the Committee speaks of the beautifully equipped but very little used government laboratory at Ottawa. For the information of the Committee it may be stated that in addition to the twenty-two inspection districts into which the territory of Canada has been divided it has been found necessary to establish three, not one, standardizing laboratories. These are located at Ottawa, Winnipeg and Vancouver. Experience taught us early in the electrical inspection work that one laboratory at Ottawa could not be used for the whole country, the distances being so great. It was found that no matter how carefully we might calibrate the inspectors' standards we could not depend on their reaching their destination in good condition if the distance was greater than five or six hundred miles. Notwithstanding the care taken in packing and the fact that our shipping boxes have been supplied with an additional bottom with springs to take the impact due to rough handling, we have found that the effect due to vibration on the trains would put the instruments out of calibration if sent on longer distances than those mentioned. Hence the necessity for creating the two branch laboratories in the west. Even under present arrangements we sometimes experience difficulties with our Halifax instruments.

Now I am not concerned very much about the "beauty" of our equipment, but I am concerned about the adequacy thereof so that the primary units of electrical measure may be accurately produced as required by the Electrical Units Act. As to the laboratories being little used, that is a question on which the Committee is evidently not qualified to speak. Had the Committee sought information on the subject it would probably have reached a different conclusion. Our inspectors' standards are required to be sent into the laboratories for adjustment and recalibration not less frequently than once in three months and oftener if the inspector has the least suspicion as to their accuracy. In this way there is a constant stream of instruments coming to and going from the laboratories. In addition to this, departments such as the Public Works, Militia, Marine and Fisheries (Wireless), are constantly sending in electrical and gas apparatus for adjustment and standardization. That the electrical companies generally do not use our laboratories more is to be regretted, for it should not be overlooked that our standards are the legal standards of electrical measure for Canada, and it would seem to be desirable that all should work from the one source or fundamental base.

The excuse given for not using our laboratories more is that the fees are too high. Let us see how this works out. The fee for adjusting and calibrating a single phase indicating or rotating standard wattmeter is \$1.25. Under the most favorable conditions it will take two men half a day to do the necessary work. If the instrument-maker has to make adjustments necessitating retests, then the time of three men is taken up, sometimes a whole day, for it must be understood that the work has to be thoroughly well done. Is the charge of \$1.25 too great under such circumstances? For polyphase instruments and more involved tests the charges are, of course, correspondingly higher. With regard to the meter inspection fee it may be stated that 90 per cent. of the meters tested come under the 60c tariff, the lowest fee imposed by any county in either Europe or America.

The report of the Committee suggests that there should

be a sort of perambulating laboratory making visits with primary standards to the different companies throughout the country. The Committee's idea of primary standards must be fairly crude if it considers for a moment that such a performance is possible. Secondary standards such as the companies and our inspectors are using can only be adjusted and standardized under laboratory conditions.

Now as to the bogie of the surplus. Taking the revenue and expenditure for the past eight years we have the following: Revenue \$997,623; expenditure \$859,468, showing an apparent surplus of \$138,155. These figures do not, as they should, include any charge for the laboratory staff at Ottawa, that is, the chief engineer, his assistants, stenographers, etc., which averages approximately \$16,300 per annum or \$130,400 for the eight years, showing the real surplus for this period to be \$7,755. The departmental accounting expense is not charged against the services.

We are aware that a propaganda has been put out by the Hydro-Electric Commission of Ontario for the purpose of placing the weights and measures system in the hands of the provinces or at least in the hands of the Hydro-electric Commission in so far as Ontario is concerned. What would be the result should the propaganda succeed? The Commission is a seller of electricity and is seeking to verify their own measuring devices. This would be tantamount to saying to a grocer "you may test your own scales and give yourself a certificate as to their accuracy." It should be clearly understood that the electricity and gas inspection services form part of the weights and measures system of Canada, and is specifically placed under federal authority by the British North America Act. Consequently an amendment to the Constitution will be necessary in order to bring the services within provincial jurisdiction.

In conclusion permit me to express my regret that the Committee did not think it worth while to consult the Department before putting itself on record with criticisms that are scarcely fair and in some instances not in accordance with the facts. Even now I would invite the Committee to a consultation in order that a better understanding and more efficient co-operation may result.

Ormond Higman,
Chief Engineer.

The Nova Scotia Board of Public Utilities has ordered a new scale of rates to be charged by the Maritime Telegraph and Telephone Company amounting to about twenty per cent. increase. It will yield about \$180,500 additional revenue, of which \$155,000 is to be paid in increased wages and the balance is consumed in taxes that have been levied since the war began in 1914. The chief feature of the increase is the establishment of the measured service system for business telephones in the city of Halifax. The business telephone flat rate is increased \$3 a year, and the maximum number of messages that may be sent for that sum is sixty per month. After that number, the charge is to be three cents per word up to 100, and two and a half cents on all words over 100. The added charge on all telephones over the province is three dollars per instrument.

The Laurentide Power Co., Ltd., Grand Mere, P.Q., has let a contract to Fraser, Brace & Co., Ltd., Montreal, for the sinking of caissons and the construction of piers for a new tail race block. Three large pneumatic caissons will be put into place this season, so that work on the completion of an addition to the power house to provide for three more units can be done with the least possible delay after the units are needed. The caissons will be ten feet wide and sixty feet long. The deepest part of the deepest caisson will rest from thirty-five to forty feet below the water level. The cost will likely be in the neighborhood of \$150,000.

Extension to the Ontario Power Company's Plant

Unique Features are Wood Stave Pipe 13½ ft. in Diameter and 6700 ft. Long
Largest Differential Surge Tank, and Power House with Walls Designed to
Withstand 40 ft. Rise in Tail Water—30,000 Kv. a. Added

Owing to the power shortage caused by the extra energy needed for essential war industries and the fact that two of the plants at Niagara Falls had reached their capacity, work was commenced in March, 1918, on an extension to the Hydro-electric plant of the Ontario Power Co., at Niagara Falls, Ontario. Completion of the work within twelve months after it was started not only adds from 40,000 to 50,000 horse-power to the plant, but also constitutes a fine record for the engineers entrusted with the work. Although the demand for energy created by the war emergency has ceased to ex-

10.5 foot diameter penstocks and two 20,000 horse-power turbines with direct connected generators, also the erection of the additional power house to house these units.

One of the Largest Wood Stave Pipes Ever Built

Unique features about this extension are the wood stave pipe, which is one of the largest ever built, the differential surge tank which has the largest diameter and has also the greatest height of any similar tank not equipped with an auxiliary spillway, and the power house walls which were de-

Section through power house extension on centre line of No. 15 unit. Also section of No. 15 penstock

ist, the demand created by the large number of new industries attracted by the power facilities offered by the Hydro-Electric Power Commission, has already appropriated a large part of the additional output provided by the new unit.

The construction of this extension involved the excavation of 133,000 yards of earth and 14,000 yards of rock to permit the placing and erection of a 13.5 foot diameter wood stave pipe 6,700 feet long, a 13.5 foot diameter steel distributor 179.5 feet long, a 60-foot diameter steel differential surge tank 94 feet high, four Johnson hydraulic operated valves, two

signed to withstand a pressure due to a 40 foot rise in tailwater elevation, this extraordinary condition having occurred in the year 1909.

The original plant of the Ontario Power Company as controlled and operated by the Hydro-Electric Power Commission, consisted of an installation of fourteen turbines, seven with a rated capacity of 11,800 horse-power, five rated at 15,000 horse-power and two at 16,000 horse-power, making a total of 189,600 horse-power. The generators, which are direct connected, have a total rating of 149,012 kv.a. Water

was supplied through two 18 foot diameter conduits, each approximately 6,600 feet long, having a combined maximum capacity of about 162,000 horse-power.

No addition to the forebay to accommodate the new conduit was necessary since the forebay and gatehouse were built to accommodate a third conduit.

The existing No. 1 conduit, which is of steel plate construction, was installed in 1903, while No. 2 conduit, which is of reinforced concrete construction, was installed in 1910. This second conduit, when inspected in April, 1918, after being in service eight years, showed no signs of deterioration, although a velocity of 25 to 28 feet per second had been maintained

This thimble, which projects 2 ft. from the concrete reducer, extends $1\frac{1}{2}$ ft. into the wood-stave barrel. The union between the wood, and the thimble was sealed by tightening the bands around the staves. Connection with the surge tank and penstocks is made by means of a steel distributor, the diameter and length of which are 13.5 and 179.5 ft., respectively. The steel distributor is united to a section of reinforced concrete pipe leading to the surge tank. The concrete pipe is laid on a horizontal curve, the end of which bends upward through 90 degs. to form an elbow connection with the centre of the bottom of the surge tank.

The excavation for the trench for the wood stave pipe

during operation, nor was there any vegetable growth whatever appearing on the walls.

Features on New Conduit

No. 3 conduit, the one recently constructed, is 13.5 feet inside diameter. The staves are of B. C. fir 4 inches thick by 6 inches wide and banded with $7/8$ inch diameter steel bands, in two sections with two shoes. The pipe is carried on timber saddles spaced at $4\frac{1}{2}$ foot centres except where the pipe is concreted in place. Connection is made with a 20-ft. diameter thimble at the gatehouse by means of a reinforced concrete reducer 25 feet long. The connection between the wood stave pipe and the concrete reducer is made by means of another steel thimble 13.5 ft. in diameter and 6 ft. long.

line was handled from the cut by shovels, derricks, and locomotive cranes. The difficulties in this work were varied and in some places severe, due to the close proximity of No. 2 conduit and to large quantities of water which were encountered at the upper end of the pipe line and at Dufferin Island crossing. A portion of the excavation was deposited along the sides of the cut for back-fill while the remainder was placed on dumps located at convenient points.

Saddles Supporting Pipe

The saddles used to support the pipe are built-up timber sections so constructed as to make a continuous form for the lower half of the pipe. Mud sills were used under the saddles through the earth cut, in order to distribute the load of

the pipe and prevent settlement as far as possible. Through the rock cut the mud sills were left out and the lower limits of the saddles were placed on the rock which was evened up to grade after excavating the trench. They served also during the construction work as forms for the lower half of the conduit. These saddles were designed not only to support the finished conduit in its proper line and grade; but also to prevent diametrical deformation caused by uneven settlement of backfill, or uneven hydrostatic pressure, when the pipe may not be running full. Prevention of spreading of the upper ends of the saddles is obtained by cantilever action in the

were used as patterns from which to lay out the corresponding steel plates. The patterned plates later were sheared, punched and assembled and bolted to the distributors to insure their assembly in the field.

Penstocks Nos. 15 and 16 which deliver the water to the two new turbines in the power house are 216 feet in length. Each penstock ends in a supply pipe with taper connections bolted to the spiral casings of the turbine. The steel plate used in the construction of the penstock varies in thickness from $\frac{3}{8}$ inch at the upper end to 13-16 inches at the lower end. The supply pipes are constructed of 13-16 in. plate

Excavation at site of power house extension

upper 3 ft. of the ribs of the saddles. The cantilever action is obtained by the stiffening effect of two $\frac{3}{4}$ -in. bands in each saddle, which enter the structure of the saddle about 3 ft. below the tops of the ribs, which pass around under the lower side of the conduit and which react against heavy cast-iron washers braced against diagonal offsets in the ribs of the saddles.

Drainage of Pipe Trench

On account of the bottom of the trench being below the water level in the Niagara River for the greater portion of its length it was necessary to provide ample drainage for the pipe trench. For 1,000 feet at the upper end, and 825 feet at the lower end, the pipe is concreted in place. This was necessary in order to allow the pipe in these sections of the trench to be backfilled and thus restore the surface of the park to its original condition.

Steel Distributor to Connect Penstocks

The steel distributor at the lower end of the wood stave pipe is made of $\frac{5}{8}$ inch steel plate and is 13.5 feet in diameter and 179.5 feet long. Four penstocks are connected to this distributor by means of bell-mouthed tees made of $\frac{1}{2}$ inch steel plate. The distributor is incased in concrete so as to allow the surface of the park above it to be restored to its original condition. A section of 13.5 foot diameter reinforced concrete pipe 77 feet long connects the distributor with the surge tank. The tees connecting the penstock are riveted together in sections cut from beaver board patterns. In preparing the patterns, wood frames were built around the shop-assembled distributors in such a manner that the framework resembled joists or ribs shaping the tees. The beaver board strips were tacked to these joints, were match-marked and

throughout. The penstocks are designed for a pressure equal to 150 feet of head at the upper end, increasing to 320 feet at the lower end, these figures including pressure rise due to a turbine gate closure time of three seconds, with relief valve closed.

After the penstocks were erected the space between the excavation and the outside of the pipe was filled in with lean concrete. This holds the penstock in position and protects the outside from corrosion.

Unit stresses adopted in designing the penstocks to resist the static heads only, exclusive of metal provided to compensate for corrosion, were 15,000 lb. per sq. in. for tension, 10,000 for shear and 20,000 for compression. The desirability of maintaining maximum joint efficiency necessitated a change in the type of longitudinal joints as the thickness of the shell changed. This efficiency was maintained by adopting triple riveted lap construction in longitudinal seams in plates varying from $\frac{3}{8}$ to $\frac{7}{16}$ in., and by adopting triple riveted butt construction in the seams in plates thicker than $\frac{7}{16}$ in. Single riveted lap construction was adopted for the circumferential joints.

Penstocks and Surge Tank

The new penstocks drop vertically through 48.3 ft. from the distributor, then bend 45 degrees and extend 99 ft. toward the power house, and then bend 45 degs. more and extend horizontally into the power house. Each penstock tube, which is surrounded by lean concrete containing a 12-in. drain discharging into the corresponding draft tube, terminates in a reducer with two openings making 90 degs. horizontal bends from the axis of the horizontal portion of the delivery end of the penstock. The flanges on the openings of a reducer

are bolted to the metal casing of the turbine. The steel plates for the penstocks were assembled in place. Two 10-ft. and two 10.5-ft. valves responding to hydraulic control are set with their top ends approximately 20 ft. below the centre line of the distributor.

The surge tank is of the Johnson differential type, 60 ft. outside diameter and 78 ft. high. The tank is built of steel plate varying in thickness from $\frac{1}{4}$ inch plate at the top to one inch plate at the bottom, while the internal riser, 12 ft. in diameter and 60 ft. high, is built of $\frac{1}{2}$ inch plate. The roof for the tank is constructed of steel roof trusses with wood covering. Anchors with turnbuckles connect the trusses with the riser to prevent vibration during load changes. The steel bottom of the tank is constructed of $\frac{1}{2}$ in. flat plates, field riveted, resting on a carefully levelled 2-in. grout course spread over a thin concrete footing poured on the solid rock.

The water wheels are double runner, central discharge turbines with spiral casings, running at 187.5 r.p.m. and delivering 20,000 horse-power under 180 foot head. The turbine gates are operated by vertical servo-motors which are controlled by actuators mounted on the gallery. These actuators are equipped with distance speed controllers, hydraulic hand controllers, gate limiting device, manual speed adjuster, gate opening indicator and tachometer. The pressure oil for operating servo-motors is furnished by a helical gear rotary

388 and the walls designed to withstand pressure due to water at this elevation on the outside power house. This necessitated an unusual amount of reinforcing steel. The steel work for the interior columns, roof trusses and crane was designed to act independently of the walls, so that it could serve in place of falsework for the erection of the machinery.

Hydraulics of Plant

The hydraulics of the plant are of more than ordinary interest, due to the fact that each of the three pipe lines and surge tanks that have been installed differ considerably. For this reason an excellent opportunity is presented of making a comparison of their respective hydraulic characteristics and capacities.

No. 1 tank has very little capacity and is of the simple tank type. Its only function is to limit the surge pressure on conduit No. 1 during load changes and provides entrance to a spillway for discharge of water at times of load rejection.

No. 2 surge tank, of the Johnson differential type, was the first tank of this character ever built. This tank serves the double purpose of relieving pressure surges and furnishing or storing water during load changes while the velocity in conduit No. 2 is being accelerated or decelerated. It is also equipped with a spillway as an additional safeguard, to prevent spilling over the top at times of abnormal surge, and to

Surge tank floor assembled ready to lower onto foundation

pump, delivering 62.5 gallons per minute against 200 lbs. pressure. The sump tanks are each of 350 gallons capacity and are provided with screens for cleaning the oil before it is returned to the pressure tank.

Power House Designed for Severe Stresses

The power house is of concrete and structural steel construction. In the substructure plain concrete has been used throughout except for the concrete over the draft tubes, which has been reinforced for the upward pressure, which will occur with high water in the river. The generator pits, air ducts and sump well are also reinforced to prevent injury developing from the temporary severe loading of portions of the structure during the erection of the units and from vibration when the plant is in operation. In the superstructure reinforced and plain concrete and structural steel are used.

In order to protect the power house against a recurrence of the high water conditions which prevailed in 1909, the window sills in the front and end walls were placed at elevation

limit the height which would have been required without this provision.

No. 3 surge tank is of the same type as No. 2, but has no spillway. Its design is such that full load rejection under the most abnormal conditions will not cause overflow.

During 1913, a series of tests was made to determine the hydraulic characteristics and carrying capacities of conduits Nos. 1 and 2, also of penstocks Nos. 1 to 14, inclusive. The results of these tests indicate some very striking facts regarding the relatively greater carrying capacity of concrete pipe as compared with riveted steel and also the exceedingly smooth surface that can be obtained with concrete if proper and careful construction methods are used.

The Electrical Equipment

The generating equipment consists of two 15,000 kv.a. 75 per cent. power factor maximum rating, 3 phase, 25 cycle, 187.5 r.p.m. horizontal shaft water wheel type generators. These generators will have approximately the same over-all

Bottom sections of spiral casings of turbines Nos. 15 and 16

dimensions as the 8775 kv.a. generators originally installed for the Ontario Power Company, by the same manufacturer. Each generator will require 60,000 cubic feet per minute of air to enable the machine to carry its rated load with the specified temperature rise. The scheme of ventilation involves, (a) the enclosure of the sides of the generator armature and rotor above the floor line and the top of the generator pit around the machine with a sheet steel housing; (b) the installation of a pair of motor-driven blowers for each generator to deliver the required volume of air into the generator pit, and, (c) the use of fan blades on the generator rotor to force the air from the pit through the ventilating ducts in the machine. One blower unit is used on each generator for normal operation, the other blower acting as a stand-by.

Three exciters will be installed in connection with these two machines, 125 kv.a., 250 volt, direct driven by 185 h.p., 2,200 volt, 3 phase induction motors. These, as well as the generators, are being supplied by the Canadian General Electric Company; also the 200 h.p. starting auto-transformer and the necessary switching equipment and Tirrill regulators for the exciters.

The new construction was carried out under the direction of the technical staff of the Hydro-Electric Power Commission of Ontario, of which Sir Adam Beck is chairman and F. A. Gaby is chief engineer. The technical staff responsible for the design and construction includes H. G. Acres, hydraulic engineer; T. H. Hogg, assistant hydraulic engineer; M. V. Sauer, designing hydraulic engineer; E. T. Brandon, electrical engineer; A. H. Hull, assistant electrical engineer; A. V. Trimble, construction engineer; Walter Jackson, resident engineer; J. F. McGraw, general superintendent of construction; F. A. Bugar, field superintendent.

The contract for the structural steel for the extension was awarded to the Standard Steel Construction Company, Port Robinson, Ontario. The erection of the steel was carried out by the construction department of the Commission. The Pacific Coast Pipe Co., Vancouver, B.C., supplied the wood staves for the pipe line. The generators were made by the Canadian General Electric Company and the turbines by

the S. Morgan Smith Company, York, Pa. Other materials and equipment were supplied as follows: Bands and washers, Steel Company of Canada, Hamilton; shoes, Malleable Iron Company, Owen Sound, and Pratt and Letchworth Company, Brantford, Ontario; steel distributor, surge tank, penstocks, valve casings and supply pipe, Canadian Des Moines Steel Company, Chatham, Ontario; Johnson valves, Larner-Johnson Valve and Engineering Company, Philadelphia, Pa.; pressure regulators, Wellman-Seaver-Morgan Company, Cleveland, Ohio; turbine governors, the Lombard Governor Company, Ashland, Mass.; servo-motors, Canadian Allis-Chalmers Company, Toronto; gate valves, Chapman Valve Manufacturing Company, Indian Orchard, Mass.; blowers, Canadian Blower and Forge Company; potheads, Standard Underground Cable Company, Hamilton; conductors, Eugene Phillips Electrical Works, Montreal; switches and bus bar supports, General Devices and Fittings Company, Chicago, and A. H. Winter-Joyner, Ltd., Toronto.

Montreal Harbour Contracts

The Montreal Harbor Commissioners have let the contracts for the equipment for the electrification of the harbor. A large number of tenders were received. The Canadian General Electric Company will supply the generator set, switchboard, lighting transformers, etc., for the substation; the contract includes a 1500 h.p. synchronous motor, direct-connected to two 500 kw. 1200 volt generators. The overhead catenary apparatus goes to the Northern Electric Company, Ohio Brass Company and the Canadian General Electric Company. The Standard Underground Cable Company of Canada will supply the control wires; the Canada Wire and Cable Company the feeder control wires and the Steel Company of Canada the steel stranded wires. The contract for the wooden poles has been let to Lindsay Brothers, represented by Mr. Irving Smith, Montreal, and that for the steel poles to Wonham, Bates and Goode, inc., Montreal. The work of construction will be commenced about the 1st of September and will be carried out by the Commission's staff.

Wireless Telephone Transmitter for Seaplanes

Flying Boat Type Developed by the American Marconi Company for Navy Use During the War

By Mr. E. J. Nally

Marked progress in the perfection of airplane wireless telegraph and telephone apparatus is a direct result of exhaustive researches in radio communication which have been conducted during the past two years. Light-weight transmitters having a sending range of 150 miles or more have been developed. Spark apparatus has been employed to a considerable extent in airplane communication, but transmitters utilizing the vacuum tube oscillator have the advantage of permitting either speech transmission or telegraphic signals by damped or undamped oscillations, at the will of the operator.

Practical wireless telephone apparatus of the vacuum tube type is disclosed in the following description of the Marconi type S. E. 1100 set—a comparatively high power bulb transmitter—developed by the Marconi Wireless Telegraph Company of America.

The set was designed primarily for the large flying boats, the H-16 class, of the U.S. Navy, and has fully satisfied every test to which it has been put. In one of the earlier tests in flight over Chesapeake Bay, telegraph signals radiated from a trailing antenna on an H-16 boat were heard distinctly in Washington, D.C., over a distance of 120 nautical miles. Subsequent tests with the set used as a wireless telephone permitted the accurate transmission of speech over a distance of 150 miles. The transmitter radiates at two wave lengths, 1600 to 600 meters. For the former wave length a trailing wire antenna of .0004 mfd. is employed; for the latter, an emergency aerial of .00026 mfd.

The transmitter is supplied with two 3-electrode tubes of the pliotron type. One tube is employed as an oscillator for the production of radio frequency currents, and the other as a modulator and amplifier of the voice currents communicated to it by the microphone.

The fundamental circuits of the set are shown in Fig. 1, the actual circuit in Fig. 2, a wiring diagram showing the function of the change-over switches in Fig. 3, an installation sketch in Fig. 4.

Description of the Circuits

For best understanding of the operation of the apparatus, it should first be appreciated that if the grid and plate circuits of a vacuum tube include radio frequency circuits coupled inductively, conductively or electrostatically, alternating currents of any desired frequency may be generated. This is the first requisite; other problems, such as rapid change of wave length, satisfactory modulation, and the elimination of disturbing capacities between circuits, arise in the practical set, and are of equal importance. They were satisfactorily solved only after diligent research.

In order to set valve circuits into a state of radio frequency oscillation, it is necessary that the connections be so made that the grid end of the grid inductance will be alternately negative and positive as the plate end of the plate inductance is positive and negative. When the grid and plate radio frequency circuits are coupled with the proper phase relation, any variation of voltage in either the grid or plate circuits will cause minute disturbances in the oscillation circuits, setting them into oscillation at whatever frequency they happen to be adjusted to. For example, a slight variation of voltage in the plate circuit by any means whatsoever, will cause its resonant circuit to oscillate at radio frequency, and the resultant currents will act upon the grid

circuit, setting it into oscillation at the same frequency. The resulting radio frequency fluctuations of the grid potential will act upon the plate at the right time to keep the plate resonance circuit in a state of oscillation, and this state of affairs will continue so long as the proper supply of voltage and filament current is maintained, but not otherwise.

The tube is able to generate alternating currents because of its amplifying properties. The energy delivered to the grid circuit in accordance with the actions just outlined will gradually increase in value until a maximum is reached, which is the maximum output the valve is capable of delivering, as may be discerned from the well-known characteristic curve.

Referring to Fig. 1, it will be observed that the plate and grid circuits of the tube contain the coils L_1 and L_2 , in inductive relation, each connected through the condensers C_2 and C_1 to the negative side of the filament. The grid oscillating circuit comprises the coil L_2 , the condenser C_2 and a protective condenser C_1 . The plate oscillating circuit includes the condenser C_3 , a part of the coil L_1 and the series condenser C_4 . The antenna and earth connections tapped off from the coil L_1 take the place of the condenser C_3 in the grid oscillating circuit. C_2 is called the balancing condenser. In series with the grid is another condenser C_5 shunted by a leak resistance R_1 , which maintains the grid at a negative potential.

The system further includes a three electrode tube F', G', P' which amplifies the output of the microphone circuit and simultaneously modulates the output currents of the oscillating bulb.

It will be noted that the plate circuit is fed by a 1500 volt d.c. generator G_2 , the positive terminal of which connects to the plate P of the oscillating tube through the audio frequency inductance or transformer L_3 and the radio frequency inductance L_4 . The negative side of the generator connects through the milli-ammeter A_1 to the negative side of the filament F . The condenser C_6 is the protective condenser which is generally employed in tube oscillating circuits when the source to the plate circuit is connected in shunt to the plate and to the filament, as is the case in this circuit. The modulating circuit shown to the right of the drawing permits either voice transmission or telegraphy by damped oscillations.

Circuits for Wireless Telephony

For telephony, the microphone M is placed in series with the telephone induction coil P_1 , S_4 , and the battery B_1 , by means of the switch S_1 . The coil S_4 is connected to the grid and filament of the modulating tube, and includes in its circuit the battery B_2 through which the grid is held at a suitable negative potential for maximum magnification. The filament and plate of the modulating tube are shunted across the plate circuit of the oscillating tube. The audio frequency choke L_1 may be said to act as a one to one transformer. The radio frequency choke L_4 prevents the radio frequency currents developed by the oscillator from flowing back to the plate circuit generator G . C_7 is a protective condenser for the plate circuit generator.

When the transmitter M is spoken into, speech currents of variable frequencies generated by the microphone are impressed upon the grid circuit of the the modulating tube,

Fig. 1—Fundamental circuits of the wireless telephone transmitter for seaplanes

and, through the medium of the auto transformer L_3 , alternating currents are superposed upon the plate circuit of the oscillator. This in turn varies the amplitude of the oscillator currents at speech frequencies, and accordingly the amplitude of the radio frequency oscillations flowing in the antenna circuit. It is essential that the key K_1 of figure 1 be closed for the production of undamped oscillations, for when it is open the tube stops oscillation. Manipulation of this key permits telegraphic signalling by the undamped oscillations produced by the tube.

Telegraphy by Damped Oscillations

When it is desired to telegraph by damped oscillations, the change over switch S_1 is thrown from the microphone to the buzzer B which is energized by the battery B_1 . The interrupted currents fed by the buzzer through the primary P_1 of the induction coil produce alternating currents of higher voltages in the coil S_1 , which in turn are magnified by the modulating tube, the latter varying the radio frequency currents in the oscillator tube at the frequency of the buzzer. In this way, the antenna radiates damped oscillations in groups, the frequency of the groups varying as the number of interruptions of the buzzer.

A more detailed circuit of the Marconi aircraft set appears in Fig. 2. This diagram not only embraces the fundamental connections of Fig. 1, but includes all necessary switches for the different signalling functions on the 600 and 1600 meter wave. It includes, moreover, a detailed wiring diagram of the filament circuits.

Details of the Filament Circuit

The filament circuit divides at the positive terminal of the 24 volt storage battery B_3 , one branch going through the rheostat R_1 to the filament F of the oscillating valve, and the other going through the rheostat R_2 to the Filament F'

of the modulating valve. The negative sides of the two filaments are connected together and to ground. In addition there is provided a potentiometer P_2 connected across across the battery B_2 with a tap leading to the negative potential battery B_2 and on through the secondary of the microphone transformer S_1 to the grid G' .

The object of the potentiometer in Fig. 2 is to compensate for any loss of negative potential in the grid circuit G' , which may be occasioned by the lowering of the voltage of the filament battery B_1 .

The switches for shifting the connections from one system of signalling to the other are enclosed in drums. The schematic diagram of these is shown in Fig. 3. The inside and outside rows of jaws on each set are represented by the upper and lower group of dots in Fig. 3. In that figure the left hand pair constitute the wave length changing switch, the middle pair, the sending and receiving switch, and the right hand pair, the signal switch. The first, second and third positions of each switch are indicated by the letters X, Y, and Z, these letters being placed between the two points which the blades of the switch short circuit in that position.

Regarding the action of the oscillating valve itself: When the grid is negative in respect to the filament, no current passes between the grid and filament; but when it is positive, considerable current passes which constitutes a loss in the circuit; but if the grid is held at a constant negative potential this energy is reduced and a more effective transmitter is obtained. The grid potential may be held at a negative value by the insertion of a grid battery, but it can be done in just as effective a way by inserting a condenser in the grid circuit which rectifies the grid currents and holds the grid at a negative potential.

If the leak were not provided, the potential of the grid

Fig. 2—The actual circuit used in practice

would rise to such a high negative value that all action would be stopped. A leak of proper value definitely limits the maximum negative potential of the grid and, therefore, does away with the necessity for a special grid battery.

Change-Over Switches

The numbers on the separate single pole switches in Fig. 3 correspond with those shown in Fig. 2. The outside row of studs on the wave length changing switch perform the following functions: In the 600 meter position (X at 32 in Fig. 2) the first tap on the upper section of the loading coil L_1 is connected to the plate series condenser C_1 , and at 43 short circuits the end portion of the same coil. In the 1600 meter position Y, it connects at 32 the second tap of the coil to the condenser and opens the short circuit.

The inside row of studs on the wave length changing switch performs the same functions for the coil L_2 , which is the lower portion of the long single coil mounted in the middle of the rear of the panel in the accompanying photograph. In the schematic diagram, Fig. 6, the blade marked 35 is shown connecting to the first tap of the lower portion of the coil in the 600 meter position, and to the second

the "send" position the circuit of the antenna at 50 is through the series condenser C_8 to the top of the loading coil L_2 , and to the ground. The latter is connected at 49 through the antenna ammeter A_2 to the main ground bus of the set which is the frame.

The inside portion of the "send-receive" switch, in the lower part of Fig. 3, is idle in the receive position Y, but the "send" position X at 21, it completes the 1,500 volt d.c. supply current to the plates P and P' of the pliotrons. At 52 it connects the primary of the microphone transformer P_1 to the microphone terminals 28 and to the buzzer B. These connections are opened in the "receive" position.

There are three positions for the signal switch. The first, X, is for continuous wave telegraphy. In this position the connections made in the second and third positions are opened. The second position Y is for telephony; the inside portion of the switch (the upper part in Fig. 3) connects the microphone to the microphone battery, and at 51 the outside portion (in the lower part of Fig. 3) completes the filament circuit for modulating valve and short circuits the key at 47. In the third position, the switch connects at 30 A the buzzer to the microphone battery, and at 51 keeps

Fig. 3—Wiring diagram showing the function of the change-over switches

tap in the 1600 meter position to the grid condenser C_8 with its leak resistance R_1 . The actual wiring of the set differs slightly from this, for it was found that the same tap of the coil was correct for both wave lengths. For this reason, there are but two taps on the lower portion of the coil. The first of these is coupled directly to the grid condenser C_8 and does not go through the wave length switch. The blade marked 42 short circuits one end of the coil L_2 in the 600 meter position and removes the short circuit in the 1,600 meter position.

The switch marked XY in Fig. 3 serves to connect the antenna A_6 to the transmitter in the "send" position (X) and to the receiver in the "receive" position (Y). In

the filament of the modulating valve lighted, removing the short circuit from the key.

The position of the switches in Fig. 3 does not correspond with their location on the set. All three switches are built to stand a maximum of 10,000 volts high frequency potential, although the potentials developed in the apparatus are considerably lower.

Meters and Their Functions

Space and weight considerations demand the fewest possible measuring instruments. A direct current ammeter A_4 is connected in series with two filaments and reads the total current taken by both of them. The instrument's scale

registers from zero to 10 amperes; to read the current in either filament it is merely necessary to cut out the other one. This may be done by means of two small switches marked on the set "oscillator filament" and "modulator filament."

The principal indicator for checking up the proper operating conditions of the set is the plate current drawn by each of the valves from the dynamotor, the voltage of which, as already mentioned, is 1,500 volts. This reading is obtained from the plate current ammeter A_1 of Fig. 2, connected in the ground leg of the supply circuit. This instrument reads from zero to 300 milliamperes and measures the total plate current taken by the oscillator and modulator. The maximum voltage developed by the dynamotor is 1,600 volts, and the vacuum tube generally will cease to operate when it falls below 1,100 volts. The generating tube will oscillate over a wide range of plate voltages if the filament current is kept below a certain critical value. The filaments of the pliotrons are designed to operate on 18 volts.

Wiring

The entire set is wired with No. 12 B & S bare soft copper wire with empire cloth tubing slipped over it as insulation. No terminal lugs are used; the ends of the wires are bent in the shape of an eye which fits the stud terminal and is passed around it in a direction that tends to make the wire grip the stud when the nut is tightened.

The wiring has been so located that small or disturbing capacities between the wires are avoided.

Structural Considerations

Owing to the vibration of the airplane every possible precaution has been taken to prevent the fastenings working loose. Special steel lock washers are used throughout the set. The general scheme of construction is such that the main supports and fastenings will bend before they break, wood or any material which splits or fractures, having been eliminated. The steel wire cross braces shown in the photograph make the structure an extremely light and a surprisingly rigid unit.

Power Supply

The primary source of energy is two 12 volt, 50 ampere hour batteries of the Willard lead type similar to those used in automobile starters. The filaments of the two pliotrons are operated through a rheostat directly from the 24 volt storage battery. Since the tubes require a plate e.m.f. of 1,500 volts d.c., a small dyna-motor, driven by the 24 volt storage battery, is supplied. The armature has two windings in the same slots, one connected to the 24 volt commutator at one end, and the other to the 1,500 volt commutator at the opposite end. It is a two-pole machine excited from the 24 volt source. The armature, which runs on ball bearings at 5,000 r.p.m. and draws about 30 amperes on its full load at 450 watts, weighs approximately 30 pounds.

In addition to the 24 volt storage battery, three other batteries are required; two for the transmitter and one for the receiver. These three sets are known as the microphone battery, grid battery and receiver battery. The voltage of the first is 5; of the second 60, and of the third 40. The 60 and 40-volt sets consist of 20-volt units connected in series. They are arranged in a wooden box screwed to the operating shelf. A dilecto terminal block is supplied.

The Support of the Pliotrons

To insure against breakage, the best position for the pliotrons is vertical with the large neck at the bottom. This brings the plate terminal cap at the top and the filament and grid terminal cap at the bottom. In each of the two dilecto rings shown at the top of the photograph, three

spiral springs placed 120 degrees apart support a spring cap which fits over the plate terminal cap of the pliotrons. The springs are held by small machine screws which pass through the insulating ring. One of these serves as a terminal, being connected by a pig-tail to the spring tap. In each of the two bottom dilecto rings, three spiral springs, placed 120 degrees apart support a special jack block made to take the filament and grid terminals. This block is made in two halves, upper and lower, held together by screws; clamping these spring jacks between them, three posts,

Fig. 4—Sketch showing the installation of the complete set

which project from the bottom of the jack block, take the ends of the three supporting springs, and are electrically connected by a copper pig-tail to the screw-eyes that hold the other end of the spring to the dilecto ring. The two filament terminals of the tube and the grid terminal are brought out to the three screws in the dilecto ring. Thus each pliotron is supported to the rigid frame of the set by 6 springs which are set so that when the tube is in place the top springs pull down and the bottom springs pull up.

The mechanical period of vibration of the vacuum tubes in this spring mounting is considerably below that of any vibration that will occur in the seaplane itself. Sudden shocks in any but a horizontal direction are not transmitted through these springs with sufficient violence to injure the tubes.

The positions of all controlling appliances on the main panel board are clearly indicated in the photograph, Fig. 3. The small sub-panel is mounted immediately to the rear of the frame.

Reel Antenna and Accessories

The antenna reel group for this set consists of the reel mechanism, a removable drum with antenna wire and spare drums with complete antennae on them. The wire from the reel runs through a take-off pulley and passes through the lead-in insulator in the side of the hull of the boat. It then passes through either a strut pulley or wing pulley, depending upon the type of the boat.

Reel Mechanism

A cast aluminum plate, clamped to one of the main struts in the hull of the boat, carries a shaft on which the

drum turns. On this same shaft, next to the attachment plate, there is a brake drum of cast aluminum, and around this drum a cast iron brake band. The band is sprung over the drum and prevents it from turning except when a cam which is attached to the brake lever springs it open. A pin on the brake drum engages holes in the main drum, when the latter is put on the shelf. The crank by which the main drum is turned has a square hub on which the drum sets. It is slipped onto the shaft, and latches in place. The latch is released by a latch handle just behind the arm of the crank. To remove the drum, to put a new one in place, the operator grasps the arm of the crank, and in so doing also grasps the latch handle and releases the latch. He then pulls the crank and drum off together. One drum may then be slipped off the hub of the crank and a new one put on, and the two slipped back onto the shaft.

Reel Drum and Antenna

The drum is a pressed steel spool, black japanned, and will hold about 600 feet of the standard antenna wire. It has a square hole at its centre which fits the hub of the crank. The antenna wire has a ball at the reel end, and this ball is dropped through a hole in the drum face. The other end of the wire is attached to a swivel, and this in turn is attached to the "fish" or weight.

Lead-in Insulator

The lead-in insulator is a moulded "electrose" fitting, with a metal tube running through it, and a wide flare at either end, so that the wire cannot catch on the ends of the tube even if it enters at right angles. The insulator is held by lock-nuts in a hole in the side of the hull. The antenna connection from the set is brought to this insulator. When the antenna is out, the ball on the reel end of the wire rests against the inside flare of the insulator. The wire is thus entirely disconnected from the reel, and the reel is dead. When it becomes necessary to reel up, the ball is grasped, and of course brings the wire with it. The ball is passed through the take-off pulley and dropped through the hole in the drum face, and the crank is turned. The brake mechanism is arranged so that the cam may be left holding the brake off during the reeling-up process.

Fig. 4 shows the position of the receiving storage battery, the main storage battery transmitter, transmitting key, receiver, and battery box.

The maximum antenna current is 2.5 amperes, with the antenna supplied with the set. This has been found to satisfy all ordinary distance requirements.

The New 70,000 KW. Turbine of the Interborough Rapid Transit Co.

The Interborough Rapid Transit Company, New York, has recently placed in operation at its 74th Street power house, a turbine rated at 60,000 kw. capacity continuously, and 70,000 kw. for two hours; it is, therefore, the most powerful in the world. It has three elements, one high pressure and two low pressure, and is the first triple cross-compound turbine to be placed in operation.

The new unit occupies a floor space of 52 x 50 ft., and is about 19 feet high. The high pressure element receives steam at 205 lbs. gauge pressure, and superheated 150 deg. F., and exhausts it into the low pressure elements at 15 lbs. gauge pressure. The two low pressure elements are identical in construction, and each receives one-half of the steam from the high pressure element and exhausts it into the condenser where a 29 in. vacuum is maintained. All three elements operate at 1500 r.p.m., and each drives a generator rated at 20,000 kw. continuously, 23,500 kw. for two hours,

and 30,000 kw. for a half hour. The generators deliver three-phase, 25-cycle, 11,000 volt alternating current.

The Turbines

Though consisting of three separate elements, the entire machine is started, synchronized, and controlled as a single unit. At the same time, any one or two of the elements can be shut down without interfering with the remainder, so that the high efficiency of a single large machine is combined with the flexibility of three smaller machines. In addition, the three small elements are mechanically much stronger than a single large one would be; the temperature differences in any cylinder are considerably less, and commercially common materials, with moderate blade speeds and stresses, can be used.

All of the turbines are of the pure reaction type, without the usual impulse elements, as this construction is considered preferable in view of the great volumes of steam to be handled. The high pressure turbine is of the single-flow type, and is made of cast steel. The low pressure turbines are of the semi-double flow type; that is, the steam enters near the centre of the turbine and flows as a whole through a portion of the blading, and then divides into two portions, each of which flows through a separate section, into the condenser. Since the low pressure turbines must receive high pressure steam in case the high pressure turbine is shut down, the central portions of these turbines are made of cast steel also. All three rotors are equipped with Kingsbury thrust bearings, in order to prevent axial movement.

The Generators

The generators are so connected to the bus bars that any combination of them can be operated in parallel. In practice, however, all three are brought up to speed together, and synchronized through a single oil-switch connecting the generator busses to the main bus. Reactance coils are installed between the various busses, which limit the amount of current that can flow between the generators. Should a short circuit develop in any of the feeder circuits, or a burn-out occur within a generator, the generator affected is disconnected from the busses by a circuit breaker without interfering with the operation of the other generators.

The method of synchronizing the generators is as follows: The field current is first applied to all the generators, and then the throttle valve of the high pressure turbine is partly opened. As soon as the high pressure rotor starts revolving, it will start the rotors of the low pressure turbines through the field current. All three then come up to speed together in correct phase with each other. They are then synchronized with the system and connected to it by closing a single circuit breaker.

The governing mechanism must not only control the unit as a whole, but also each turbine operating separately. Some of the operations performed by the governors are as follows: If serious electrical trouble develops on the circuit of one of the generators of the low pressure turbines, a circuit breaker will disconnect this generator from the buss bars. Relieved of load, the turbine begins to speed up, but before its speed has increased four per cent. its governor shuts off the steam supply from the high pressure turbine. This, of course, raises the back pressure of the high pressure turbine, and a back-pressure valve opens allowing part of the exhaust from the high pressure turbine to pass into the atmosphere, while the remainder goes into the other low pressure turbine. In the meantime, the first low pressure turbine, being without steam, shuts down. When its speed reaches three per cent. below normal, the governor admits high pressure steam, and the turbine continues to operate at this speed until the

switchboard operator either shuts it down or restores normal conditions.

Should the generator of the high pressure turbine be cut out of circuit, the governor cuts off practically all the steam to the entire system, leaving just a sufficient flow to maintain the speed of the high pressure turbine now without load. The speed of the two low pressure turbines decreases, and when the frequency drops three per cent., the governor admits high pressure steam direct to the low pressure turbines, which then continue operating. The switchboard operator can now either restore matters to normal or shut down the high pressure turbine.

Each turbine also has an emergency stop, which will operate automatically in case the governor fails and the turbine begins to race, or it can be tripped by the switchboard operator.

When one of the turbines fails with the entire unit heavily loaded, the governors permit each of the remaining turbines to carry the maximum load of 30,000 kw. This can be maintained for a half hour, which is regarded as sufficient time to get other generators into operation, and thus relieve the overloaded turbine.

Condensers

The condenser equipment consists of two 25,000 square-foot surface condensers for each low pressure turbine. There are four circulating pumps, three Le Blanc air pumps, and four condensate pumps. All of these pumps are turbine driven (the air pumps directly and the others through gears), and all are so arranged that one or more can be put out of service without interfering with the operation of the condenser.

Performance

The steam consumption of the entire unit at its point of best efficiency is 10.7 lbs. per kilowatt-hour. The high pressure turbine and one low pressure turbine, operating together, consume 12 lbs. of steam per kilowatt-hour; and one low pressure turbine alone consumes 14.25 lbs. The total steam consumption at full load is 826,000 lbs. per hour.

The equipment throughout was manufactured by the Westinghouse Company.

The Swiss Railways Extend Electrification of Their Lines.

The introduction of electric traction on the lines of the Swiss Federal Railways has in these latter years, on account of the acute shortage of coal occasioned by the war, received the foremost attention of the authorities and has now emerged as a very practical economic question. The principal nerve of the Swiss railway system is government owned. The electrification of these lines is simplified by the vast store of unused water power which the country possesses. According to an official survey, verified in 1914, including the storing and improvement of lakes, the water power of Switzerland is capable of producing an energy equal to 2,173,000 horsepower. If old plants were replaced by new ones it is even estimated that the highest efficiency of the total water power reserves could be raised to as much as 3,000,000 horsepower. On January 1, 1914, the electric power already in use in Switzerland amounted to 887,000 horsepower. The Swiss Confederation owns some 1800 miles of the entire railway system of the country of 3,216 miles. Of the 1,416 miles owned by private companies 622 miles are already electrical, but only an insignificant percentage of the government railroads has so far been operated by electricity.

The first important Federal standard-gauge road to be chosen for electrification was the Gothard Railway, one of the important international highways, featuring moreover, in many sections the brilliantly conceived engineering of mountain railways. The electrification of the 68 miles section

Erstfeld-Bellinzona was approved in 1913 and it is expected that it will be opened this fall. This section, with 28 per cent. of its length consisting of tunnels and a grade of 2.5 to 2.7 per cent. for 25 miles, was chosen for an experiment because of its enormous traffic with Italy, which caused large consumption of coal with resulting smoke in the tunnels. The sections Bellinzona-Chiasso and Erstfeld-Lucerne are expected to follow in 1921. A series of plants yielding 70,000 horsepower is planned for eastern and central Switzerland.

The cost of electrification of the Erstfeld-Bellinzona line is estimated at \$8,000,000. The cost of electrifying the entire Federal railway system is estimated roughly at \$200,000,000.

In 1918 the electrification of the following railways using steam traction was decided upon and work on them commenced at once; the sections of the Federal railroads Sten-Brigue and Berne-Thun; the section Hasle-Langnau of the Emmenthal Railroad and the section Bevers-Filisur of the Rhaetian Railroads. The to-be-electrified section Sion-Brigue will be a continuation of the electrical traction Simplon tunnel which was opened for traffic in 1906, with its northern exit at Brigue. The Berne-Thun line, connecting with the electric Berne-Lotschberg-Simplon railway, which latter was inaugurated in 1913, has already been opened for traffic in May last. It now provides excellent and frequent train connections between the Swiss Capital, the Bernese Oberland resorts and—in connection with the Lotschberg line—the Valais and Northern Italy.

The new locomotives which are being used by the Swiss Federal Railroads on the section Berne-Thun, besides those of the Berne-Lotschberg-Simplon line, are each equipped with four single phase, alternating current motors, each of 450 horse-power. The electric parts were furnished by Brown-Boveri & Company, Baden, and the mechanical parts by the Swiss Locomotive and Machine Company of Winterthur. The electrification works on the Bevers-Filisur line were completed by the middle of last April and from April 16 steam engines have been duly replaced by electric motors, the current being supplied by the power station of Bevers, which furnishes the necessary energy for the Engadine lines which were electrified in 1913.

New Books.

Electric Power Transmission—by Alfred Still, professor of electrical design, Purdue University; second edition, revised, enlarged and re-printed; McGraw-Hill Book Company, Inc., 239 West 39th Street, New York, publishers; price \$3.50. When this book was published originally under the title "Overhead Electric Power Transmission" its suitability as a college text book was not seriously considered. The author states that it has, however, been used by a large number of technical schools and colleges and in this second edition changes have been made which should enhance its value as a college text without detracting from its usefulness in the field of practical engineering. The principal addition is an entire chapter treating of underground conductors. The following chapter headings indicate the scope of the work: Electrical Principles and Theory—Elementary; Economic Principles and Calculations; Electrical Principles and Calculations; Insulation of Overhead Transmission Lines; Protection against Lightning—Transient Phenomena; Transmission of Energy by Underground Cables; Transmission of Energy by Continuous Currents; Mechanical Principles and Calculations—Overhead Conductors; Transmission Line Supports Inductance of Transmission Lines with any Arrangement of Parallel Conductors; Specification for Wood Pole Transmission Line; Specification for Steel Tower Transmission Line. Well illustrated; 400 pages; size 4 x 9 inches, in McGraw-Hill standard cloth binding.

The Contractor-Dealer

Power and Light in the Country—The Farmer and Other Rural Dwellers Want the Advantages of Town Life, Without Its Drawbacks—A Golden Sales Opportunity

Many people do not yet realize that we are just on the eve of a tremendous development in the use of farm lighting and power plants. As an example of their confidence in this field the Northern Electric Company state that each month they use some twenty Canadian farm papers and that up to August 1 over three million and a half advertisements had been placed in Canadian farm homes.

The farmer has his telephone, his rural mail delivery, and his automobile. Now he wants a water supply in his home like they have in the city, and light and power appliances to take the place of the servants they can't get. There are a few cases where central station lines supply the need, but in the vast majority of cases this is not so. The small gasoline-electric power and light plant is the solution.

It is not generally known, either, that in Canada and the United States there are somewhere between one hundred and twenty-five and one hundred and fifty different firms manufacturing farm power and lighting plants. Some of these do not carry on a very aggressive campaign, but the number of real live firms is considerable, and the amount of publicity being distributed among the farmers and other rural dwellers is, in the last five years, simply colossal, as is indicated by the one instance quoted above.

A big question is—who's selling these plants? We were asked the same question the other day and naturally replied—why the contractor-dealer, of course. We got the answer, "You're wrong. We've tried to interest the contractor-dealer for years and now have about given him up. The contractor-dealer isn't a salesman. He ought to be, but he isn't." If this is true, it's too bad, and we're afraid it is quite true. This means then that someone else, quite outside the electrical business—some one in the salesman class—is going to cash in on this big business of selling power plants all over the country.

And to think, too, that the profit on one of those plants is as great or greater than the profit on a house-wiring job—with none of the uncertainties of the contractor's business.

Yes, it seems to be a fact that the men who are selling these plants—doing it easy, too—are anything but electrical men. Down in London this week, the Northern Electric Company has a convention of all their agents in Western Ontario, and it is said there isn't an electrical man among them. But they believe in these plants for the farmer—they have been sold the idea themselves, in salesmen's parlance—and so they are able to go out and "sell" the farmer. Mr. T. R. Campbell, from the head office of the company, is down in London, reading a paper to the "boys," and we got him to let us have a few extracts. They are of general interest and so are reproduced below. Perhaps they will help to convince some contractor-dealer that he is missing a good thing.

Expected Growth of Country Towns

The automobile industry affords an excellent comparison of what may be expected of the power and light plants within the next few years. Since 1914 the increase in the number of automobile licenses in Canada has increased three hundred per cent., the following are the exact figures:

1914—	69,598
1915—	89,944
1916—	123,464
1917—	197,799
1918—	275,746

Of the total amount for 1918, 114,376 were in the Province of Ontario. It is safe to say that of this three hundred per cent. increase, the growth in rural districts has been as great, if not greater, than in the cities. Furthermore, this growth has taken place during the war period. I recently visited fifty farms in a representative farming district, and found that only six people did not have automobiles, and only eight people stated that they did not intend to have an electric plant in two years or less. Thirty-eight of the parties visited had read our advertisements and had become interested in farm plants. Four people were sold plants on this trip, all of whom had never been called upon before.

We believe that practically every prospect will have a plant in three to four years. By prospects we mean these residents in your territory who have reasonably good buildings, and are able to buy a plant without financial sacrifice. We do not want to encourage anyone to buy a plant, who cannot afford to do so without mortgaging his property, or going into debt.

The idea of electricity on the farm must always be sold before an order for the plant is placed; in fact, when you have finally sold the idea, the taking of the order is a simple matter. Keep your prospect's mind on what will do him the most good, even when the price comes up, you have a chance to score. Do not say, this machine is \$1,000.00 and this one \$500.00, as your prospect will begin to think that perhaps one machine is cheap and no good and the other one unnecessarily high. Get his mind off the price entirely, because he is not yet solid on the idea of electricity. Do this. Say, "Mr. Brown, let us see what size plant is best suitable for your needs." Take him to the stable and walk through the various buildings, go into the cow barns, the horse barns, the big pen and every other building, and say, "You should have so many lights here and a switch beside this door to turn on the lights as you enter. Here you will need an outdoor lamp on an arm for lighting the yard; there should be another light in the carriage driveway, one here in the garage, and another in the dairy." By this time your prospects has begun to see that electricity means light everywhere and you have got him coming along. Then go through the house in the same way, but be sure to have Mrs. Farmer with you on this trip. Then this is the time to talk washing machine, separator, churn, etc., and prospects question of price can now be brought about when his mind is in the most receptive mood.

People buy things only when they are shown a certain definite reason why they should part with their money. This reason must be made to stand out in their minds, of greater importance than the price. The thing to be bought must

either be an absolute necessity; be useful; save the prospect money; provide him with greater safety; give him greater comforts; provide him with pleasure; satisfy his pride or improve his living conditions. Think of several things which you have recently purchased, and see if every one of these was not bought for one of these reasons. Some may have been bought for two or three reasons, as the automobile—it is often really necessary, always useful and surely a source of pleasure. Lightning rods are hardly necessary or useful, they are bought solely to provide safety. Food is bought because it is necessary. Farm tools because they are useful. Buildings are painted to save money. Insurance is bought for safety. New furniture for greater comfort; a cigar for pleasure, and an expensive hat or pair of shoes to satisfy one's pride. Now look at an electric plant and see if you can find any other single article which can be purchased for as many reasons.

Necessary.—The real necessities of life are **Light, Water, Power** and **Food**. And electric power and light gives you three of them.

Useful.—A thing that does but one important thing and does it well is useful. What then of one that will wash and iron clothes, clean house, churn, run separator and milking machine, turn grindstone, wash dishes, pump water for house and stock, light every room in the house and every stall in the barn, charge the auto battery and do a dozen other things.

Save Money.—Everyone likes to save money, but in an electric plant, "money saving" is combined with "better results." To do it electrically is to do it cheaper, better and quicker. Your prospect will want proof of this. The labor of one man is saved in turning a grindstone, running a separator, pumping water for the stock, running the churn, washing machine and in milking, grinding, etc. Remember man-power is equivalent to $\frac{1}{8}$ h.p., with the present labor costs including board, and other expenses, every hour of man labor costs 30c. A horsepower will do the work of eight men and at a cost of less than 10c. per hour. It works when you want it to work. Does not have to be paid when idle, requires no room, board, nor washing, never goes on strike, gets sick nor takes Sunday off. An investment for a power and light plant pays a dividend 365 days every year. Compare this with the dozens of machines that the farmers buy, which are used only a few days each year, but have come to be considered as a necessary expense. Reapers, drillers, ploughs, mowers, etc., are not absolute necessities, but it has been found that they pay. To do work in the old-fashioned way would mean that a farmer could not produce his crop at a price which would enable him to compete with others using more modern devices. They have therefore come to be regarded as necessities. These machines each do one thing and one thing only and only for a few days a year. How much better investment, therefore, can anyone ask than a machine which is useful, provides safety, assures comfort, increases pleasure, etc., and is used every day and every night. These very facts must appeal to the judgment of every thinking man.

Safety.—An electric plant may rightly be called a "Safety First" plant. Think of the dangers of a lighted lantern in the barn, the upsetting of a lamp, loose matches, the kerosene can in the wood shed, and how these dangers are eliminated by an electric plant.

Comfort.—Every farmer wants his family to have comfort. It has been demonstrated that the reason why the large number of young folks leave the farm is due largely to the lack of conveniences. Give them the comforts of running water in the kitchen, the bathroom with hot and cold water, and do away with the out-door pump.

Pleasure.—There is real pleasure in an electric plant, pleasure for everyone. Children will enjoy their play more. Women folks will find their work in every room in the house, brighter and easier. It will be a pleasure for the man to turn on the various lights in the stable as he goes about his chores.

Pride.—Every man likes to have a good home, and to think that his family has as much, or even more than his neighbor. If the prospect were to sell his home and had an electric plant, it would be one of the most important things he would feature, and it would go a long way towards increasing the value of the farm. The proudest man in any community is the owner of an electric plant. It will be the most talked of thing on the farm, by the farmer himself, his wife and every member of the family. The same satisfaction of pride goes with an electric plant as in the purchase of a thoroughbred cow, or a fancy driver or a high powered six.

Improved Living Conditions.—Improved living conditions simply means better surroundings, giving one's children a better time, and make their lot in life a whole lot easier than ours has been. Happy homes are made happier by an electric plant. People living in the country have many things which are greater natural comforts than those of the city. There is plenty of air, trees, wild strawberries to pick, and fish to be caught in the brook, but how are these things to be enjoyed? One must stay in the house doing that work, which it seems is never finished. They say that folks from the city who spend their vacation in the country get more real pleasure out of the country than the farmers themselves. It is simply because they are more free to enjoy those things. Canada is essentially a country of home-loving people. These homes have been built after much hard labor. The prairies have been broken and the railroads and telephone lines have brought people closer together. Days of development and pioneering are over in most sections. Now the enjoyment of these years of labor is to be reaped by the pleasure of real comfort, prosperous home life. This is what improved living conditions mean.

It is not to be expected that you will take the time with every prospect, to go over these various points, but you should in every case figure out which argument would best appeal to the prospect. I have known cases where a man bought wholly on account of the dread he had of lighted lanterns in the barn; the Safety Argument appealed to him strongly. Another farmer will have excellent buildings and every convenience but light. The argument of saving money or the necessity of light, may not appeal particularly strong to him, but to add to the completeness of this farm and enjoy those greater comforts, which he can well afford, is undoubtedly the best way to appeal to him.

I have found in selling plants to farmers, or in fact anything, the first thing is to get acquainted and then get the confidence of the prospect and his family, it will then be found that the sales will follow much easier. Many plants have been sold on the first visit, but as a rule it does not do to crowd the prospect too hard, it is better to make three or four calls, than to attempt to close on the first visit, and get such a definite turn-down, that your return is not welcome.

Just a few words about Accessory Sales and Service. In going over your district, you should regularly drop in on those plants which are already installed. These trips can be really profitable. The plant may be touched up a little or names of prospects obtained and some accessories sold. Endeavor to impress on your prospects that you are there to help them in every way; you will then find the business coming easy and it will be a short time before your name will become inseparably connected with everything electric for the farm.

National Association of Electrical Contractors and Dealers Hold Successful Convention

By K. A. McIntyre

Monday and Tuesday were given up to meetings of the National Executive Committee, which also held sessions Saturday morning and in the evenings of Monday, Tuesday and Thursday, giving to the convention a "stick-to-business" air which was the occasion of favorable comment by outside observers. The Canadian representatives on this committee, Mr. E. G. Mundy, for Western Canada, and Mr. Kenneth A. McIntyre for Eastern Canada, were present, and took part in the deliberations for the first time.

The routine business of the National Association is conducted by the executive committee, leaving the convention free for a full program of instructive papers and discussions. The two most important subjects before the executive committee were those of the Bureau of Education and Research and of a National Labor Policy.

Announcement was made by National Chairman W. Creighton Peet that the \$100,000 annual fund for the Bureau of Education and Research was practically assured, and that actual steps would soon be taken by putting men in the field. We will see this most important plank of the Goodwin Plan in early operation, improving the dealer as a merchant and the contractor as a man of business.

Some fourteen hours of debate were spent over the question of a National Labor Policy, a subject which has been avoided by the association for fifteen years. The principles were sent on to the convention by the executive committee with the recommendation that they be adopted by the association and returned to the executive committee with power.

On Wednesday morning came the opening session of the convention with National Chairman Peet in the chair, and addresses of welcome by Mr. Burrill, Wisconsin State Chairman, and by Mr. Corcoran, Acting Mayor of Milwaukee, who cordially and humorously turned over the keys of the city. The official photograph was taken following this meeting.

Beginning on Tuesday the Canadian delegation began to arrive, until finally twenty were on hand to represent the Dominion. We were all given a cordial welcome and made to feel right at home. A snap shot of the delegation appears in this issue showing the Canadian party with Messrs. Goodwin, Chase, Comstock and Corcoran. Mr. F. J. Allen, general manager of the Benjamin Electric Manufacturing Co. of Canada, and Mr. W. M. Andrew, secretary of the Canadian Electrical Manufacturers' Association and the Canadian Electrical Jobbers' Association, were also in attendance at the convention though not in the picture.

Mr. Frank Stockdale gave one of his popular talks at the afternoon session on the subject of "Keeping up with rising costs" which developed into an all-round lecture on merchandising with an interesting discussion following.

Messrs. Albert Uhl and E. S. Morley of the Chicago Estimators' Association, gave talks, illustrated with lantern slides, on estimating and overhead, following through actual estimates. Those of us who are familiar with conditions in our business in Toronto, (represented by only three members), could see in these facts a reason for the wide variation in Toronto quotations on electrical construction. Our Toronto and other Canadian members cannot expect to learn more about their business unless they show enough initiative to get out and learn. On one job in Toronto prices varied from \$13,000 to \$23,000. On one Chicago job estimated before the convention five Chicago quotations varied from \$43,600 to \$45,217 and without collusion. These results are attained by investigation, study and education. Surely they are worth while, yet some members are "too busy" to

go to the convention—possibly too busy losing money.

Tuesday evening was given over to a reception and dance in the Fern room of Hotel Pfister, the convention headquarters. Suffice it to say that our party had a most enjoyable evening.

At 8.30 Wednesday morning several special suburban cars left with all delegates and ladies for Waukesha Beach, a pleasant spot on Peewaukee Lake about 30 miles from Milwaukee. First was given a talk on the problem of absorbing the alien into the life of the community, eliminating the weak points shown in the national policy during the war both in Canada and the United States.

Mr. Goodwin (it was "Goodwin Day") once more surprised us all by repeating nothing he had said before. At the conclusion of his remarks he introduced Mr. Corcoran of the General Electric Co., Schenectady, who promises to be Goodwin the Second. Mr. Corcoran talked very successfully against time, the hour being late, and everyone regretted that he had not hours longer to tell us more. By the most unique and original methods he proceeded graphically to impress upon his audience the principles and opportunities of merchandising electrically. These talks and papers will be reproduced later in this publication.

More than 500 were in attendance at the convention, but there seemed to be many hundreds more electrical people at Waukesha, especially when gathered together for luncheon in the large pavilion. One table was reserved for the Canadian delegation with Messrs. Goodwin, Chase, Peet, Comstock, Stearnes, Corcoran, Kalischer. The afternoon was wisely devoted to sports, the ladies' events being of particular interest. Many took advantage of the opportunity for a swim in the lake and were well rewarded. Returning to Milwaukee, the evening was free for sight-seeing except for members of the executive committee who don't even know what Milwaukee looks like.

Friday morning was devoted to the meetings of several sections in order to give those interested in special features an opportunity to hear papers on subjects to their liking. "Methods of Determining Value of Burned Out Apparatus," by A. O. Kuehmsted, Gregory Electric Co., Chicago. "What Constitutes Efficiency in the Repair Business" by A. Penn Denton, Kansas City, Mo. "Methods of Dealing with the Public," by C. M. Jamison, Milwaukee Ry. & Light Co. "Arrangement and Conduct of a Retail Store," by Phil Polacheck, Milwaukee. "Relations of the Dealer to the Public in Merchandising" by J. R. Tomlinson, Portland, Ore. "Fixture Business as a Part of Retailing," A. L. Oppenheimer, Cleveland. Meeting of state and local secretaries with Mr. Wilson of Massachusetts in the chair.

In the afternoon Dr. H. C. Metcalf of the Bureau of Industrial Research, New York City, gave a splendid address on "Human Relations in Industry." Next was brought before the convention the question referred to above in regard to a National Labor policy. After considerable discussion, the principles were adopted and sent back to the executive committee, recommending that a committee of five be appointed to carry the matter further. Routine business completed the sessions.

On Friday evening was held the annual dinner, with an enjoyable menu, enthusiastic singing led by the famous James R. Strong, vociferous applause and a feeling of non-alcoholic exhilaration. Dancing followed and then regrets that the 1919 convention was over, and hopes that we would all meet again in Baltimore, Md., October 6th, 1920.

Saturday morning the executive committee met, disposed of the balance of business and authorized the national chairman to appoint the committee of five to carry on with the national labor policy. This committee, since appointed, consists of Messrs. Comstock, New York, chairman, Hixon,

(Boston), Stearnes, (New Orleans), Sanborn, (Indianapolis), McIntyre, (Toronto).

The convention was a great success and Mr. Oppenheimer of Cleveland, convention chairman, Mr. Burrill, Mr. Brauns and others of the Milwaukee committee, deserve the greatest credit for their successful efforts. The ladies were well looked after during their stay, a very complete program of entertainment being provided.

The convention must be considered a success in every way and every Canadian member who availed himself of this opportunity to have a little holiday came home well pleased with his investment.

The following is the personnel of the Canadian delegation referring to the photograph herewith:

The Canadian Delegation.

1st Row, Left to Right.

L. H. Lander, Electrical Contractor, King St. E., Hamilton, Ont.

E. A. Drury, Electrical Contractor, 164 Oakwood Ave., Toronto, Ont.

Kenneth A. McIntyre, Beattie-McIntyre, Ltd., 72 Victoria St., Toronto, Ont.

H. H. Gardiner, Masco Co., Ltd., 91 Queen St. E., Toronto, Ont.

J. S. Latrobe, Chas. A. Branston Co., 355 Yonge St., Toronto, Ont.

2nd Row.

L. K. Comstock.

S. A. Chase.

W. L. Goodwin.

J. A. Corcoran.

3rd Row. (Not including large man standing)

F. T. Groome, 119 Fairview Ave., Toronto, Ont.

E. C. Clarke, The Clarke Electrical Co., 68 Harvard Ave., Toronto, Ont.

A. S. McCordick, Canadian General Electric Co., Ltd., 212 King St. W., Toronto, Ont.

A. C. Lyons, Lyons Elec. Co., Brantford, Ont.

A. W. J. Stewart, Toronto Hydro Electric System, 226 Yonge Street, Toronto.

J. A. Dynes, Elec. Cont. 20 Avalon Place, Hamilton, Ont.

4th Row.

E. G. Mundy, Mundy, Rowland & Co., Standard Bank Bldg., Vancouver, B. C.

F. O. Ellis, Ellis & Howard, Ltd., 9-11 Queen St. N., Kitchener, Ont.

F. M. Davis, Northern Elec. Co., Ltd., 131 Simcoe St., Toronto, Ont.

A. W. Lamont, Canadian Westinghouse Co., Ltd., 158 Portage Ave. East, Winnipeg, Man.

A. S. Edgar, Canadian General Elec. Co., Ltd., 212 King St. W., Toronto.

J. F. S. Madden, Hydro Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.

Chas. A. Branston, Chas. A. Branston Co., 355 Yonge St., Toronto, Ont.

Not in Photo.

F. J. Allen, Benjamin Elec Mfg. Co. of Canada, Ltd., 11 Charlotte St., Toronto, Ont.

W. M. Andrew, secretary Canadian Associated Mfrs. of Elec. Supplies, secretary Canadian Elec. Supply Jobbers Association, Stevenson Building, Toronto, Ont.

The Servant in the Home

Take advantage of the scarcity of servants to advertise the service of electrical appliances.

Have you a servant in your home?

If so, is she satisfactory?

or

Pretty hard to get a faithful

servant these days?

is a good introduction to an offer to supply "something just as good—or better" in the form of washing machine, dish washer, vacuum-cleaner, etc., etc. The servant question is one that interests every passer-by. Take advantage of it to impress upon the householder that the electrical home is a very fair approach to—and the only available substitute for—the good old times.

Renewable Cartridge Fuses Stand Heavy Test

The M. B. Austin Co., manufacturers of the Trico renewable cartridge fuses, is represented in Canada by J. D. Lachapelle and Co., Montreal. These fuses have been tested by the Underwriters' Laboratories, Chicago, who report that "the design of these fuses, the quality of material employed, and the workmanship shown indicate that they have adequate mechanical strength to resist the forces incident to their use as protective devices for the circuits for which they are rated." In a circular issued by Lachapelle & Co., it is stated: "The Underwriters' tests have been completed and we have successfully passed all of their requirements for every size of fuse which we make, including from one to 600 amperes on the 250 volt size, and from one to 600 amperes on the 600 volt size. No other fuse manufacturer of renewable fuses has ever secured such an approval."

If there are any Contractor-Dealers or Jobbers who are doing anything unethical in their merchandising let them stick to their own pastures and not look over the fence into somebody's pasture where they think the grass is a little greener than in their own. Let them keep their covetous eyes trained on their own problems and work them out on ethical business lines. You, gentlemen, know what I mean by that. I do not have to state: "Don't cut prices. Don't graft customers by cut-price methods."—S. A. Chase.

How I Increased My Sales 100%

By A Wiring Contractor

What is the matter with us contractors anyway? I used to be the same as the rest, but latterly I believe I'm getting a little common sense. It wasn't so very long ago that I used to scrap with my competitors over a \$75 job as if my business existence depended on it. Think of it—cutting prices on a job that at best would yield us a \$25 profit. And the provoking part of the whole thing was that the man for whom you were doing a cut-price job didn't seem to care—he'd spend money on other things like water. But the wiring—that was merely looked upon as a necessary nuisance.

That was about the time I began to see things differently. "These men don't care about wiring," I said to myself. "Then why sell them wiring? Perhaps they DO care about the service, the convenience and luxury that follows a good wiring job. I'll try them."

And I did try them and let me tell you it has worked wonders in my business. There are times now when my customer will stand for a \$200 or \$250 job when formerly he would have grouched at \$75. He sees it from the other side, that's all. I talk to him so he sees himself in a cosy arm-chair with a handsome floorlamp to read his evening paper; feels the warmth of a cosy-glowing radiator on a chilly evening; tastes the crispest of toast and sips the most delicious coffee for his early breakfast. Then I explain the advantages of an electric range, its low operating cost, the sanitary features, its safety and labor-saving qualities and so on and on. There isn't a man who builds a house who doesn't mean to have all these things in a little while and the wiring contractor is largely to blame that so many of the new homes are badly wired.

So I hardly ever talk price to a customer any more. I sell him, instead, an electrical home. I find that's the only thing about my business they're interested in, so why cloud the issue with details?

I'm just a wiring contractor and haven't yet begun the sale of appliances, but my common sense tells me the right thing to do is to open a nifty little store. For customers I'll have all the houses I wire, in addition to as many more transients as my windows can catch. In my district there are two hardware stores selling electrical goods, but they just hand them out like monkey-wrenches. I think our goods should be sold by people who understand them and appreciate their value—and can sell some "service" with them, too. It sometimes seems to me the manufacturer makes a mistake letting just anybody handle his goods, but perhaps fellows like me are to blame for not having good, attractive stores; I'm going to try it out anyway.

Principles of Electrical Precipitation

A treater for electrical precipitation is a comparatively simple structure. The accompanying schematic diagram illustrates a typical pipe treater. In general it consists of two large horizontal flues connected together by a number of small vertical pipes. Gases enter through one flue, pass through the other flue to a stack, exhaust fan, or other draft producer. The gas is then exhausted into the atmosphere. Some treaters are operated with an up draft, some with a down draft, according to the particular local conditions to be met. Some treaters employ rectangular passages instead of pipes to connect the two flues. These are generally referred to as plate or box type treaters. The principle of operation for all these types of treaters is the same.

The actual precipitation of the dust or fume occurs in the vertical pipes referred to above. Carefully centered in each,

is suspended a small wire or a small chain. These constitute the negative electrode of the treater system. The inside surface of the pipes constitutes the positive electrode. Each wire or chain is carefully insulated from its pipe and from the ground, and is charged to a high potential usually at from 25,000 to 65,000 volts direct current. The tubes themselves are grounded. Thus within each pipe is created an intense electrostatic field. The gases passing through this field become ionized, and the ions travel with high velocity in a di-

Schematic Diagram of Electrical Precipitation Pipe Treater

rection at right angles to the electrodes causing the field. These highly charged ions are continually colliding with the suspended solid and liquid particles in the gas, and the ions impart a charge of like potential to such particles, which in turn begin to travel towards the electrode of opposite polarity. Since the negative suspended electrode is of much smaller area than the electrode formed by the inside surface of the pipe there is much greater electrostatic stresses per unit of area in the neighborhood of the wire, and as a result far greater ionization about the wire. Thus the gas receives a static charge of the same polarity as the wire, and the solid or liquid particles in the gas receive charges of this same polarity which causes them to be projected against the inner surface of the pipes, where they tend to stick and accumulate until the electric power is turned off, after which the accumulation of dust is usually collected from the pipes by loosening it by rapping the sides of the pipes and collecting the dust in hoppers at the bottom.

Specialist in Insulating Materials

Mr. John T. Rowe has established himself in Montreal as a specialist in electrical insulating material. He has had a wide experience in the electrical field, having spent ten years in the designing and working out of various kinds of electrical instruments as well as nearly two years in the wireless section of the Royal Air Force. Mr. Rowe specializes in supplying the most suitable insulation from specifications and drawings of prospective electrical work and is the Canadian representative of the Imperial Porcelain Works of Trenton, N. J., and also represents the Wilmington Fibre Specialty Co. and the General Insulate Co.

Rose & O'Hearn, electrical jobbers and supplies, 220 King Street West, Toronto, have moved to 293 King Street West.

The City of Westmount has reduced the charge for electrical lighting from 5c to 4¾c per kw.h. The charge for cooking remains at 1½c. per kw.h.

Advertising Pays

A contractor-dealer out in Alberta increases his fan sales by displaying prominently each day in his window a large card bearing some such legend as the following:

PROBABILITIES:

Fine and Very Warm To-day and Tomorrow.

No heat prostrations where electric fans are used. Come in and get cool.

His newspaper ads. take a similar form, being always located in the same place, come in for regular inspection by the reader each morning..

The Star Electrical Vibrator

W. H. Spencer & Co. Ltd., Montreal, are distributors of the Star Electric Vibrator, manufactured by the Fitzgerald Manufacturing Co., Torrington, Conn. The vibrator,

it is claimed, relieves aches and muscular fatigue that are the result of cramped or overstrained muscles and stagnated circulation.

Prepare for the Long Evenings

The longest day is nearly two months behind us and it's not too early to be planning for the long dark evenings. This winter will see a big sale of fixtures and portable lamps which are ever growing in popularity. Perhaps the most noticeable development in house lighting is the appreciation of the fact that fixtures and portables are in reality part of the furniture

Lighting Fixtures are "Furniture"

of the home. It is not enough that a room should be well lighted or even artistically lighted. The fixtures, the stands, the shades should all blend with the rest of the decorations. How frequently people move their furniture around to get better effects or refurnish entirely, but how rarely do we hear of them discarding their old lighting fixtures. Here is a growing field for the retailer. Act on the assumption that yours is a part of the decoration of the home just as much as if you were selling furniture, rugs or hangings.

The aeroplane race from the Canadian National Exhibition to New York and return during the progress of the Big Fair in August will be the first international event of its kind ever attempted. The idea behind the contest is to demonstrate the commercial feasibility of aerial transportation between Toronto, New York and intermediate points.

Tell the Public Where to Get "Service"

Wouldn't it be a good idea for electrical contractor-dealers to put on a general campaign explaining why electrical devices should be purchased from electrical men? You don't go to a grocery store for monkey-wrenches or to a shoe store for a new hat. Why go to a hardware store for electrical equipment? It would surely have a very beneficial effect on the whole situation if it were explained to the public that they will get more sympathetic and intelligent attention in the electrical store; that they will find there a larger and more up-to-date selection of goods; that the salesmen in electrical stores are equipped to answer any questions the consumer may care to ask about his purchase, and, finally, that electrical stores stand back of their goods and make it a strong point to see that they work satisfactorily. In the past, and at the present time, the public purchases electrical appliances from other than electrical stores simply because there has been a scarcity of such stores. An advertising campaign, including all the electrical dealers in any locality would enlighten the public tremendously, popularize electrical appliances and start lots of business going in the direction of the electrical store that is now going elsewhere.

How Overhead Expense of Contracting Varies, Depending Upon the Amount of the Work

From figures compiled by the Massachusetts Association of Electrical Contractors and printed in Electrical Merchandising.

Price of Material and Labor Delivered on Job	Percentage of Overhead	Price of Material and labor Delivered on Job	Percentage of Overhead
\$200	52.0	\$2,900	25.4
250	48.5	3,000	25.0
300	46.5	3,500	23.6
350	45.3	4,000	22.5
400	44.0	4,500	21.7
450	43.0	5,000	21.0
500	42.0	5,500	20.3
550	41.2	6,000	19.7
600	40.5	6,500	19.2
650	39.8	7,000	18.7
700	39.2	7,500	18.2
750	38.5	8,000	17.8
800	37.9	8,500	17.4
850	37.4	9,000	17.0
900	36.9	9,500	16.6
950	36.4	10,000	16.2
1,000	36.0	11,000	15.5
1,100	35.0	12,000	15.0
1,200	34.2	13,000	14.7
1,300	33.4	14,000	14.5
1,400	32.7	15,000	14.3
1,500	32.0	20,000	13.2
1,600	31.3	25,000	12.2
1,700	30.7	30,000	11.5
1,800	30.1	35,000	11.0
1,900	29.5	40,000	10.8
2,000	29.0	45,000	10.6
2,100	28.5	50,000	10.4
2,200	28.0	60,000	10.0
2,300	27.6	70,000	9.6
2,400	27.2	80,000	9.3
2,500	26.8	90,000	9.1
2,600	26.4	100,000	9.0
2,700	26.0	130,000	8.7
2,800	25.7	160,000	8.5

The Walger Connector Company, Toronto, C. Jackson, agent, announce that they have changed their address from 22 College Street to 32 Front Street West. This location is not only more central but more commodious and convenient for making prompt shipments.

PHILLIPS' ARMOURED CABLES

No. 2 B. & S. 3-Conductor 25,000 Volt Cable

Paper Insulated, Lead-covered, Double Steel Tape Armoured

Supplied to the Order of
The Quebec Railway, Light, Heat and Power Company

Eugene F. Phillips Electrical Works, Limited
MONTREAL

Branches : Toronto, Winnipeg, Regina, Calgary, Vancouver

Current News and Notes

Biggar, Sask.

Work has commenced on an electric plant for the Biggar Electric Light and Power Company, Biggar, Sask.

Halifax, N. S.

Earnings of the Nova Scotia Tramways and Power Company for the first five months of their present fiscal year were \$538,565; operating expenses were \$359,229. The increase in net earnings over 1918 is \$26,489.

Kitchener, Ont.

Investigation into the condition of the Waterloo and Wellington Railway Company's lines has been made by Superintendent V. S. McIntyre of the Street Railway Commission, who is to make a report to council. It is expected that the city will shortly consider the proposal of the company to sell out to it.

Mimico, Ont.

The Toronto and York Radial Co. have increased their fares for transportation up to stop 18 on the Lake Shore Road. Previously the rate was eight tickets for a quarter, but it has now been made six tickets for a quarter. Residents in the district affected are displaying some opposition to the change and at a recent meeting the following resolution was passed: "That Etobicoke Township Council be requested to call a meeting of representatives of Mimico, New Toronto, and the township itself, to interview Sir Adam Beck in regard to the franchise rights of the Mimico division (Lake Shore route) of the Toronto and York Radial Company, with a view to expropriating the said radial line, and operating it as a public utility, and to issue debentures to buy the same out."

Montreal, Que.

The Western Quebec Power Company, Limited, has been incorporated; head office, Montreal; capital stock, \$1,000,000.

Oakville, Ont.

Work on the Hydro-radial survey through Oakville has been completed. Purchase of the right-of-way will commence at once and the construction work, it is understood, will not be delayed longer than a few months. When the radial is in operation it is expected there will be a half-hourly service to Yonge St., Toronto. The trip between Oakville and Toronto will be made, it is said in about half an hour.

Ottawa, Ont.

The Battery Engineering and Supply Company, Limited, and the Continental Storage Battery, Limited, have been granted charters. The head office of both companies is at Ottawa, Ont.

The Department of Naval Service announces the inauguration of a commercial wireless service between Canada and Bermuda. It has been established between the Canadian radio telegraph station at Barrington Passage, N.S., and the British Government station at Bermuda. These stations were erected during the war for naval purposes, but will now be used for commercial work.

Perth, Ont.

The Bell Telephone Co. is doing its share in helping to improve the town by the removal of poles and overhead wires and the placing of the wires underground.

Port Colborne, Ont.

The ratepayers of Port Colborne, Ont., recently carried a

by-law authorizing the purchase of the distribution system of the Ontario Power Company in that town.

Saskatoon, Sask.

The ratepayers of Saskatoon recently voted against a proposal to operate one-man cars in that city. By-laws proposing expenditures of \$156,200 for additional equipment at the power house and \$35,000 for extensions to the street railway system were carried.

Bids are being received by the city of Saskatoon for a new 4500 kw. turbo-generator set.

St. Boniface, Man.

Work is now proceeding on the new telephone exchange for the Manitoba Government telephone system.

Sutherland, Sask.

An electric lighting plant is contemplated for the Dominion Forestry Farm at Sutherland, Sask.

Toronto, Ont.

The Toronto Street Railway Employees Union has decided to accept the terms recommended in the report of the Board of Conciliation, of which Judge Barron is chairman.

The street-car men employed by the Toronto and York Radial Railway Company, numbering 200, are coming into the Toronto Railwaymen's Union. This union will thus have a membership of over 3,000, making it the largest union in the city.

The Toronto city council will prepare a by-law authorizing the double-tracking of the Bloor Street civic car line from High Park Avenue to Runnymede Road at an estimated cost of \$160,000.

Toronto civic car lines show an increase in revenue for July of about 25 per cent. over last year.

Moved to Larger Quarters

W. H. Spencer & Co., Ltd., electrical supplies and manufacturers' agents, have removed from 340 University Street to 213. Notre Dame Street West, Montreal. The latter premises are much more commodious than those previously occupied, and are in the centre of the down-town district. The company are in a position to carry a much larger stock, and also to make prompt shipments of an extensive line of electrical supplies.

Personals

Mr. Arthur B. Reynders, former Director of Production of the Westinghouse Electric & Manufacturing Company at East Pittsburgh has recently been made Works Manager of their East Springfield plant.

Mr. H. E. M. Kensit, who joined the C. E. F. in September, 1915, has now returned to the Dominion Water Power Branch, Ottawa. He was attached to the Canadian Engineers for two years and after being wounded on Vimy Ridge was transferred to the Ministry of Munitions of War, England, as Dilution Officer, for a further 17 months. Since the armistice he has represented the Dominion Water Power Branch as a member of the Water Power Committees now sitting in England, i.e., that of the Conjoint Board of Scientific Societies on water powers of the Empire, and that of the Board of Trade, formed at the request of the Ministry of Reconstruction, on the water power resources of the United Kingdom.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

New 4500 K.W. Turbo Generator Set TENDERS INVITED

Tenders are invited upon the following:

1st Contract 1 Steam Turbine
1 Alternating Current Generator
Switchgear Equipment

2nd Contract 1 Surface Condenser and condenser auxiliaries

Forms of Tenders Instructions to bidders, and general conditions can be obtained upon application to the undersigned.

Sealed tenders endorsed "Turbo Generator" must be delivered to the City Commissioner on or before 12 noon on Tuesday the 23rd day of September 1919.

The lowest or any tender not necessarily accepted.

C. J. YORATH,

City Commissioner.

July 18th, 1919.

Eliminate the Waste of Money on Commutator and Armature repairs by using the

"No Spark"

CARBON BRUSHES

A mint of money is wasted every year through the installation and use of brushes of an improper grade. With the correct grade of brush specified the commutator and armature last far longer and repairs are reduced to a minimum.

We will save you a great deal of expense and your engineer much worry by taking the responsibility of selecting the right grade of material. Send for our information sheet to-day.

Write for our latest bulletin.

THE NATIONAL AUTHORITY FOR TWENTY-FOUR YEARS
THE 1919 EDITION

POCKET SIZE
LEATHER COVER

"STANDARD WIRING"

TELLS YOU HOW

GENERATORS—How to install them, care for them and operate them; all their troubles and how to prevent and cure them; all diagrams showing connections for compound, series and shunt wound machines. How to operate them in parallel or in series. How to protect them and wire them in accordance with the underwriters' requirements.

MOTORS—How to install them, how to protect and operate them. The required amperes, volts or horse power when any two factors are known. How to take care of hot boxes, sparking commutators and other troubles. How to change the direction of rotation when desired. How to start and stop any kind of motor in any class of service. All diagrams of motor wiring. How to find the proper size of wire for any motor for direct current or A. C. single, two or three-phase.

OUTSIDE—Line construction, line wires, service wires, poles and their dimensions and Insulators, guard arms, guy wires, and how to install Lightning arresters.

weights, and how to erect and protect them and anchors. Tree wiring, splicing, service and fuses. Transformers with diagrams and instructions.

INSIDE WIRING—When and where to run wire. How to find the proper size of wire for current, voltage and drop, either by formula or by the tables of the book. How to wire for two- and three-phase with formulae and tables in a simple manner that anyone can understand. How to run wires through partitions and walls and where roundings exist. When and how to use conduits and just how to do it. How to make connections. The proper way to make an Outlet, Junction and Switch. How to make a complete interior conduit system. How to make a Concealed knob and tube system. How to make an electric and combination system. How to use it. How to make a gas filled lamp and the fixtures and rules required.

LIGHT AND ILLUMINATION—What is meant by proper and efficient illumination, the latest data on Mazda and other lamps of every candle power and wattage. Direct, indirect and semi-indirect illumination. How to light a room. Illumination required for various classes of service from shop lighting to public halls and from factories to small residences.

TABLES—Fifty-two tables giving every dimension, carrying capacity, resistance, weight and strength of every size of wire and cable of copper, steel and iron.

All the necessary dimensions, capacities, weights, and other data on conduits, fuses, insulators, lamps, sockets, motor efficiencies, current per horse power of motors. Electrical units and their equivalents. Proper size of wire for all classes of power, light and heating installations. The proper symbols to use to indicate on plans just what is wanted from a motor to a small snap switch with all necessary diagrams.

APPARATUS AND SUPPLIES—A classified list of the leading manufacturers of officially approved wires and wiring devices. Engines, generators, motors, appliances, fixtures, and all supplies necessary for any complete installation from a Central Station to a small cottage.

The most complete and accurate Book on Wiring and Construction published

"IT SETTLES DISPUTES AND, IF REFERRED TO BEFORE WIRING, PREVENTS DISPUTES."

"ANTI-SULPHURIC" ENAMEL

In many manufacturing plants such as engraving houses, electro-plating factories, etc., acid fumes are present to such a degree as to be decidedly destructive to exposed surfaces. For all such conditions "Anti-Sulphuric" Enamel will completely solve the problem and provide a quick drying flexible, glossy coating for the job. It is absolutely resistant to acid fumes and atmospheric influences. Use it in Accumulator rooms.

TORONTO

This Box is Finished with the New Galvanizing Process

of which we are the originators. This process gives a superb finish which is much superior to japan, both in appearance and durability. It resists the acid test.

Our New Service Box No. 1005, 30 Amp., 125 volt, double pole size 8 in. long, 5½ in. wide, 2½ in. deep. It has a carrying capacity up to standard and is approved by Hydro-Electric Power Commission.

Drop in and examine these boxes. They will indeed meet with your approval and verify the claims we make for them.

We carry a complete line from 30 amp., 125 volt up to and including 1200 amp., 600 volt, and we always have on hand from 4000 to 5000 type E boxes ready for delivery.

Form Steel Boxes, Motor Starting Switches (Steel Enclosed), Motor Drip Pans, Motor Covers, Rheostat Boxes and Accessories

EASILY SOLD

is what the dealers who handle the Edén have to say about it, with good profits, too, they add.

And they are right.

The sales of Edén Machines have increased by leaps and bounds during the past year. Women everywhere are being educated to the fact they need not be kitchen drudges, so they are buying Washing Machines and their preference has been

THE EDÉN

the time tested machine with the all metal body, and its twenty-five points of superiority.

**ECONOMY
renewable
FUSES**

Owe their enviable prestige to their consistent efficiency in performance. They are the trusty guardians of millions of circuits for thousands of users who have learned from experience that they invariably measure up to the highest standards by which fuses may be judged.

As compared with the use of one-time fuses, they cut annual fuse maintenance costs 80% because an inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.

Economy Fuses make friends for the contractor who writes them into specifications and the dealer who recommends them.

WALGER CONNECTORS

Walger 3 Way Connector

To tap feed wires in outlet boxes. Condulet, or on knob and cleat work. Insures perfect connections.

Walger 2 Way Connector

For connections, for lengthening extension wires, and for exchanging fixtures. Quick, easy, certain.

**Cut the time and the costs
on every job of interior wiring**

SPEED your work with the Walger. It eliminates blow torch and solder; it makes each connection in 1/5 the time at 1/2 the cost—and does a better job.

Better yet, every Walger installed is positive proof of a perfect connection—appreciated by every Electrical Inspector who ever went over a job.

Passed by the National Board of Underwriters, and the Hydro-Electric Power Commission, for No. 12 wire and under.

Write us for sample and descriptive folders.

Ask your jobber for Walger.

ESTABLISHED 1849
BRADSTREET'S

Offices Throughout the Civilized
World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

THE BRADSTREET COMPANY

Offices in Canada: Halifax, N.S.; Hamilton,
Ont.; London, Ont.; Montreal, Que.; Ottawa,
Ont.; Quebec, Que.; St. John, N.B.; Toronto,
Ont.; Vancouver, B.C.; Victoria, B.C.; Win-
nipeg, Man.; Calgary, Alta.; Edmonton, Alta.;
Sydney, N.S.

THOS. IRVING,

Man. Western Canada, Toronto.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a Specialist in Repairs. Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an absolutely reliable job. You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine (Profit). Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the Trade Discount (More Profit).

Others are doing it. Why not you? Write about it.

WIRES AND CABLES

YOU'VE seen it. The large Reel with the Northern Electric Company's name on either side. You can see it wherever wire work of any kind is being done. In the small hamlets and in the large cities throughout the Dominion, it is a familiar sight by the street-side.

Quality, Dependability and Service is what has made the **NORTHERN ELECTRIC COMPANY LIMITED** the largest manufacturers of bare and insulated Wire and Cable.

Our Nearest House will be glad to furnish specifications and prices on any type of bare or insulated wire and cable for electrical purposes—write us to-day.

Sangamo Integrating Meters

EXCEL IN

Accuracy, Permanency and Simplicity of Adjustment

If you use Sangamo Meters
you will have these
advantages:—

← (1) The moving element is not dismantled.

(2) The new potential coil built on the core is replaced as a unit

(3) Current Coils can be changed in a few seconds.

(4) The Air Gap does not change as all parts are dowelled.

(5) Simplicity and thoroughness of design makes faulty assembly an impossibility.

Canadian Distributors—Canadian General Electric Co., Limited

For Interurban Service

For Interurban Service

“Golden Glow” Ideal for Interurban Service

The various types of “Golden Glow” Headlights for interurban service all project powerful, penetrating, steady, non-blinding beams of “Golden Glow” light—a volume of light actually greater than the average arc headlight projects.

The secret lies in the high efficiency of “Golden Glow” greenish glass reflectors and the general make-up of the headlight through and through.

Therefore when you adopt “Golden Glow” on your cars you are buying headlights scientifically correct in principle and design.

Place your order now, and soon your cars will be headed by beams of cheery “Golden Glow.”

Universal Insulator Supports

SAVE
Time, Labor and Material

UNIVERSAL INSULATOR SUPPORTS are specially designed malleable iron clamps made in four sizes for securing Insulators to open steel framework for wiring mills, foundries, shops, bridges, piers, elevated railways, subways, train sheds—and similar structures. They are easily attached, and by their use, electric wiring for lights, motors, generators, cranes, etc., can be installed with a great saving of labor and material.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Accurate—Rugged—Inexpensive

In factory or field, the Type S set will quickly and accurately measure resistance or locate faults. It will withstand, without detriment to its electrical qualities, the knocks which such a set is bound to get. It is of the Dial Decade Type, and therefore simple to operate.

Excellent design plus quantity production enables a low price without sacrificing accuracy—ratio coils 1/20 per cent, rheostat coils 1/10 per cent guaranteed.

The removable suspended coil galvanometer deflects a millimeter per microampere. This combination—accuracy of adjustment of coils, sensitivity of indicator, ruggedness, inexpensiveness—is found only in the Type S set.

PRICE \$75.00

Purchase the Products of Canadian Mills

TO uphold the Glory we have jointly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success. The buyer and seller must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR Duty is plain; Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

Sure, Safe and Fool-proof

While the essence of Krantz service is safety first, it also carries insurance of positive operation and displays a system which is commendable for its simplicity. No live part is exposed. If adjustment is necessary the electrician may unlock the inner chamber and uncover the contacts which normally are closed and locked from the child or prying operator.

In design and finish these boards are found to add harmoniously to the appearance of any wall.

Die-Cast Metal Bushings Do Away With Clamps

Clamped fittings, because of irregularities in themselves or in the porcelain, may exert excessive spot-pressure upon your insulators. Cemented fittings work loose under continuous vibration or may crack the porcelain by reason of the cement's shrinkage.

In "FRANKLIN" Post Type Insulators, such fittings are eliminated. "FRANKLIN" construction provides metal bushings which are moulded to the porcelain.

The intimate contact of these bushings with every point of the porcelain's circumference, brings about an even distribution of strains. Thus the carrying capacity of the Insulators is multiplied, and the likelihood of a breakdown reduced to the minimum.

Freedom from flash-over points and a general structural superiority which is apparent in every detail, also recommend "FRANKLIN" Post Type Insulators to your consideration.

Other "FRANKLIN" Specialties for Generating Stations are Disconnecting Switches, Potheads, Doors for Bus and Switch Compartments, Instrument Cutout Switches, Cleat Type Insulators, Air Pressure Relays, and the new "FRANKLIN" FUSE. Write for descriptive Bulletins.

Both Appreciate the Advantages of R & M Motor Equipment

The superintendent of the factory which makes electric-driven devices likes the R & M Motor because the motors supplied him are perfectly adapted to his product. His manufacturing problems are simplified and the efficiency of his product is increased.

And the sales manager likes the R & M Motor in the product he has to sell because R & M Reliability holds business for him and reduces selling expense. He finds, too, that the name Robbins & Myers used in connection with his device creates added prestige for his goods. For many years of dominant advertising in the

leading general magazines has made R & M Quality something which is generally known everywhere.

The R & M Motor is the one motor everyone knows about. Every prospective user of a motor driven device, whether for home, office, store or factory, recognizes the R & M Motor as the best insurance of reliable service from the machine.

From both standpoints—service reliability and saleability—manufacturers find advantages with R & M Motors. And for the same reasons, dealers find maximum satisfaction and profit in the sale of devices so equipped.

No. 17

Building Electrical Appliance Industry Without Proper Foundation

It is a waste of time and energy trying to sell a customer an article he can make no use of. Yet that, in effect, is what central stations and dealers are trying to do when they dangle before the eye of the average householder the many advantages of electric appliances. The simple fact remains that the householder couldn't use them if he had them, and generally doesn't use them when he gets them, simply because he hasn't the proper facilities.

We may as well face the situation squarely now as later on. Household appliances can never be used satisfactorily and will never be sold successfully until the homes into which these appliances go possess the necessary outlets to make the constant use of the appliances easy, safe and sightly. It is a foregone conclusion that we can never hope to establish the use of electrical appliances in the home, as a habit, utilizing lighting circuits and lighting sockets. They have a too limited capacity; they are, as ordinarily used, not safe; they are inconvenient to get at; the result is unsightly. All these things operate against the use of appliances.

We are making it difficult for people to use electricity instead of making it so easy that they are constantly tempted to do so.

The root of solution of the matter surely lies in a campaign for the installation outlets in the baseboards or elsewhere. Since it is a matter of public safety there should be no difficulty getting our building by-laws so worded that

every house must have special appliance outlets; the assistance of architects should be enlisted to make the number of outlets as great as possible; the contractors should refuse to wire a house unless appliance outlets are included; the inspection department should refuse to "pass" a house that is not supplied with such outlets, and, finally, the central station should refuse to supply current unless a minimum of outlets are provided. Such an attitude may, at first, seem a little arbitrary, but the campaign of "education" is going so slowly that the whole industry is being stupidly retarded. So long as keen competition causes cutting of prices, just so long will our houses be inadequately fitted electrically. The whole matter could be settled summarily if the architect, contractor-dealer and central station would get together.

Engineers Will Take Part in Deliberations on Labor Problems

On September 15, in Ottawa, some hundred and fifty representatives of the various elements in our industrial life will meet together at the call of the Minister of Labor to discuss matters which particularly affect the relationship between employer and employee. There will be about sixty delegates each, representing labor on the one hand, and employers on the other, and in addition, there will be a sprinkling of delegates whose relation to the industrial life of the country is such as to enable them to take an impartial view of the situation, or of any argument that may be brought up on either side. Such, for example, will be the representatives of the different engineering and technical societies, for we understand that the Canadian members of the A.I.E.E., the Mining Institute, the Chemical Society and the Engineering Institute of Canada will all be represented.

This, after all, is a very proper function for the engineer and one, too, which his training and experience fit him well to fulfil. There will, doubtless, be much plain speaking on both sides at the conference and much evidence of old prejudices, but the technical men, let us hope, will be the leaven of the occasion which will leaven the whole lump.

Revised Recommendations re A. I. E. E.

The Development Committee of the American Institute of Electrical Engineers made certain recommendations at the August meeting regarding the publication of the proceedings. The committee transmits the opinion that it is an almost unanimous view that the proceedings do not now seem sufficiently to interest the members at large. It presents definite recommendations under the six headings of the original draft, namely: (1) Publication; (2) Organizations; (3) Activities; (4) Local Federation; (5) National Council; (6) Engineering Congress. The essential features of the recommendations in revised form are as follows:

Regarding publication. To enlarge the editorial and executive publication staffs in order to expand the Proceedings.

To publish additional matter of live interest and value to the membership as a whole without giving less importance to the fundamental advance in the art and to original investigation work.

To publish all Institute papers and occasional papers of unusual broad general interest from sections or other sources.

To publish a set of abstracts of every paper presented at every section.

To eliminate duplication of expense heretofore incurred by publishing papers in both the Proceedings and the Transactions without depriving members of the latter.

To increase the revenue of the Proceedings by secur-

ing more advertising and if necessary, to change the present size of its page.

To print advance copies of some or all sections and perhaps branch papers but limit their distribution.

Outlet Box Numbers Standardized—A Step in the Right Direction

The Electrical Outlet Box Section of the Associated Manufacturers of Electrical Supplies of the United States have adopted a standardized system of numbering for outlet boxes and covers. This action follows a suggestion made some time ago by the Electrical Supply Jobbers' Association that some method be devised to eliminate seven sets of catalog numbers in order to discriminate seven almost identical lines of outlet boxes and box covers. New catalog of the manufacturers will shortly be on the market bearing the new standardized catalog numbers. Hereafter a catalog number will mean a certain definite box, this number applying to the same box made by every manufacturer.

The method adopted is simple—no key to remember; no puzzles to clear up. The numbers have been so worked out that the first two numerals of the cover for a certain size and shape of box, will be the same as the first two numerals of the box itself. The box number will consist entirely of numerals. The cover will be designated by the insertion of the letter "C" after the first two numerals.

Standardization is a saving all along the line, and is becoming universal. When the new catalogs are distributed, all of the electrical trade, from the manufacturer to the wireman, will undoubtedly feel this saving. Some of the reasons which influenced the manufacturers in the standardization of box numbers follow:

1. There are at present approximately 1,500 different numbers used in designation of boxes and covers of various manufacturers. There are, however, less than 200 distinct types.

2. Each manufacturer now has his own system of numbering, although the use and general type of almost any box or cover is identical with that of several manufacturers.

3. Both contractors and jobbers, in placing orders, will rarely ever take the trouble to look up and use the numbers of the manufacturer with whom the order will be placed. This necessitates the editing of orders by either the jobber or manufacturer and must necessarily result in numerous errors. On orders received from contractors, the jobber will almost invariably substitute the numbers of such boxes as he may have in stock, if shipment is to be made from stock, for those specified on the order, or, in case direct factory shipment is to be made, forward the order as received to the manufacturer with whom he may be placing his box orders at that particular time. This is invariably done unless the purchaser insists upon the particular make of boxes specified.

4. The types and styles of boxes and covers have become so standardized as to be almost on the same basis as sizes of conduits; there is, therefore, no more reason why different numbers should be used to designate the same box as manufactured by different manufacturers than that different numbers should be used to designate the sizes of conduits.

5. With the various box manufacturers using separate numbering systems, it is now necessary for the device manufacturers to use as much space in listing the boxes or covers with which their receptacles, switches, attachment plugs, etc., may be used as to list the articles themselves. This is also applicable inversely; about as much space is used in the catalogs of the box manufacturers in listing the devices as in listing the boxes and covers themselves. Then, again,

it is the almost universal custom of the various box manufacturers to list the corresponding numbers of competing manufacturers. To do this requires additional space.

6. For the box manufacturers to furnish the device manufacturers with the necessary data for a proper listing, involves an enormous amount of detailed research work by the design, engineering and drafting departments of each; also voluminous correspondence. Errors are frequent. Both labor and errors could therefore be reduced to a minimum through a standardization of numbers.

7. For the various manufacturers to adopt a standard set of numbers would effect a considerable economy in catalog costs, and, in addition, reduce the volume of jobbers' catalogs. Take the sheets issued by the N.E.S.J.A.; separate sheets are now issued by this association, to show the lines of the several manufacturers. By the adoption of a standard set of numbers, these could be consolidated, and one set of sheets used to show the lines of all manufacturers. This would reduce the volume of the association catalog by from 100 to 200 pages. Same would apply to the National Electrical Contractors' Association Data Sheets.

8. The reduction in the volume of sheets would be particularly appreciated by jobbers' salesmen, as it would considerably reduce the weight of the catalog which they have to carry.

9. A jobber, in getting out a new catalog would feel no hesitancy in listing a standard set of numbers, cuts, etc., for he could so list and place his orders with any manufacturer; at the present time jobbers are frequently carrying the listing of one manufacturer's line and furnishing boxes of some other manufacturer.

10. Separate numbering systems, as now used, give recognition to substitute, which, at best, is a bad practice, and not to be encouraged. If encouraged in one line, as at present in the outlet box line, leeway is allowed for substitution in all lines.

11. The adoption of a standard numbering system would prove educational to all in the electrical business, for contractors, salesmen, wiremen, clerks, etc., would soon become familiar with any system adopted, and know that an XYZ box was a box of a particular type and for a certain use. With so many different numbers, as is now the case, this is impossible.

12. While some advantage might now accrue to the various manufacturers through familiarity of portions of the trade with their own "pet" numbers, the adaption of a standard set of numbers would prove reciprocal, and each manufacturer would benefit in about the same proportion.

13. The adoption of a standard set of numbers would in no way interfere with the various manufacturers playing up the strong points of their own lines, such as finish, detailed construction, materials used in manufacture, etc. As a matter of fact, these features could be emphasized more than is now possible. In ordering, contractor, if he wanted some particular make of box, could specify by giving the name or brand and then list the standard numbers desired. As indicated in a previous paragraph, this would reduce substitution to a minimum, eliminate frequent errors, etc. If no particular brand was specified, jobber would, of course, understand that no preference existed, and could ship from his stock or place order for direct shipment with his preference of manufacturers.

The first meeting of the Electric Club of Toronto will be held on Sept. 19. Brig.-General C. H. Mitchell, C.M.G., will be the Club's guest on that occasion.

Boiler Room Economy in Small Plants

—By M. B. Watson, M.E.*—

The cost of fuel and freight rates on fuel in the last few years have risen to such proportions that it is more than ever important to check up the small as well as the large losses and wastages in our fuel accounts.

This checking up has been carried on for a number of years in the larger plants, but in these plants the operating staff is generally large enough for each man to have only one part of the plant to attend to, and conditions can be kept more nearly constant. Also the whole plant is usually under the general supervision of a technical engineer whose duty it is to study all operating conditions in the plant, and to direct the work of the different operators in such a way that losses can be cut down to the lowest possible point. In such plants one usually finds the best types of mechanical stokers, fuel economizers, etc., which give added efficiency to the plant.

In the small boiler plant, it would not always pay the owners to install expensive mechanical devices and the care and operation of the plant is left to one or two practical engineers or firemen. It is thus of great importance that these men should study and apply methods of operating which will give the owner the most value in power or heat generated for the amount of fuel burned.

There are numerous ways in which leaks in boiler room efficiency can be checked up and remedied, but general operating efficiency can not be checked up without systematic records. These records should be intelligible to the owner or manager of the plant as well as to the operators, because it gives the manager an opportunity of comparing the value of his different operators as well as that of the different kinds of fuel used, etc.

The simplest form of records of this kind should show the quantity of fuel used and the quantity of water converted into steam. This necessitates the weighing or measuring of both fuel and water. This should not, however, be impossible, even in very small plants; for instance if the fuel is brought to the boiler room in trucks, the average of the weights of a number of trucks could be found by weighing, afterwards it will be necessary to keep count only of the number of trucks used per day, or per hour as the case may be. A number of trucks should be weighed periodically, as different men may fill the trucks to different levels, or the same man may increase or decrease his filling gradually and unnoticeably. The measurement of the water is of course rendered more difficult at times. Engineers should encourage owners to provide some kind of measuring device for their boiler feed water. If a pump is used for feeding the boiler a counter can be installed and knowing the bore and stroke of the pump, it would be simple to calculate the amount of water pumped for any known number of strokes. Of course, the ideal method of measuring boiler feed water is by means of an integrating water meter in the feed water line reading directly in gallons or pounds. Where boilers are fed by injectors, some kind of test would have to be made on the injector to determine the amount of water fed to the boiler at different steam pressures in a definite length of time. Then only records of the length of time the injector was working and the steam pressure need be recorded to be able to determine the amount of water fed to the boiler. A little ingenuity on the part of the engineer will easily surmount any difficulty of this kind.

In making calculations from these records, due allow-

ance should be made for water not converted into steam, but used for blowing out the sediment, etc. The amount of water used in this way can be easily determined, near enough for practical purposes, for example: When the plant is not operating, note the steam pressure and mark the height of the water in the gauge glass, open the blow-off cock wide for the required length of time, noting the exact number of seconds. Then start the feed pump and raise the water in the boiler to its original level, measuring the amount of water required. If possible, while making this test, operate the pump from another boiler, otherwise water in the form of steam is being drawn from the boiler. If necessary to use the same boiler, condense and measure the exhaust steam from the pump, and subtract this amount from the water pumped into the boiler, to determine the amount blown out.

The amount of water blown from the boiler during a definite length of time is thus easily calculated, if steam is at the correct pressure. Of course this can be continued and the blow-off for different pressures found.

All the water pumped into the boiler, except that drawn off, is converted into steam, and in this way records can be made to show just how many pounds of water are converted into steam.

This method may be still further refined by making allowance for the heat added by the fuel to the water which is drawn off. For example, suppose normal steam pressure to be 125 lbs. per sq. in. gauge pressure and that the normal feed water temperature is 180 degrees F. Any good steam engineering text book will show that the temperature of saturated steam at this pressure, and therefore the temperature of the water in the boiler is about 353 degrees F. The water table in the same book will show that the total heat content of water at 180 degrees F. is about 148 heat units, or B.t.u.'s., per pound of water above 32 degrees F. also 325 B.t.u.'s. above water at 32 degrees F. Thus in raising one pound of water from 180 degrees to 353 degrees F. the heat delivered to the water is about $325-148=177$ B.t.u.'s. The steam table will show that the heat content of saturated steam at 125 pounds gauge pressure, or at 353 degrees F. is about 1192 B.t.u.'s., above water at 32 degrees F. Therefore to raise one pound of water from 180 degrees F. to steam at 125 pounds gauge pressure requires about $1192-148=1044$ B.t.u.'s. Thus we see that one pound of water blown off under these conditions has received enough heat to make $177/1044=0.17$ pounds of steam. Therefore if, say, 1000 pounds of water were blown off, the heat wasted is equivalent to $1000 \times 0.17=170$ pounds of water converted into steam. Therefore, in making calculations from the above results to find the heating value of the fuel we should count this extra 170 pounds of steam as having been generated and used.

Records, such as the above, should preferably be kept on engine and boiler room log sheets, either daily or weekly, depending on the amount of information to be entered thereon. Log sheets can be made as simple or as complete as required, but engineers or others should beware of having a lot of entries made which can not be used by the head of the plant for some useful purpose. Only entries which will be of use in determining the efficiency of the plant or the operators should be provided for.

Chief engineers, or managers, should study these log sheets carefully, as by this means they can ascertain which of the firemen are most efficient, also they can get valuable information as to the relative value of different kinds of fuel, oil, etc. In this connection the chief engineer or the

*Director of Engineering, Central Technical School, Toronto.

manager should not fail to express their recognition of good work on the part of any employees, this recognition may be only verbal, or may take a more tangible form. Expression of this kind are far more effective as an incentive to the whole staff to do as well as the best than are complaints of careless or inefficient work. The man who is striving to make a good showing for himself does much better work and is much more reliable than one who is being driven to reach a certain standard.

Forty to Forty-five Per Cent. Loss

In the average small boiler plant from 55 to 60 per cent. of the heat of the coal fired is used in generating steam, the remainder of the heat being lost in about the following proportions: 35 per cent. of the heat lost in high temperature chimney gases are, however, controllable to a great extent faces and furnace walls, 4 per cent. of the unburned coal falling into ash pit.

The second of the above losses, radiation from boiler and furnace walls, is seldom under the control of the operators, in plants already installed, except in so far as proper maintenance of the settings, walls, insulated headers, drums, etc., can be carried out.

The amount of unburned coal falling through the grates into the ash pit, and the losses through high temperature chimney gases are, however, controllable to a great extent by the firemen.

The loss occasioned by the presence of unburned coal in the ash is not very likely to amount to serious proportions, because it becomes very evident. For example, suppose the grade of coal in use contains 10 per cent. of ash, and the amount of unburned coal passing through the grates amounts to 5 per cent. of the quantity fired. The residue in the ash pit contains almost half as much coal as ash, or one third of the whole is coal, which condition, being noticeable to the eye will attract the attention of the fireman, and if he does not remedy this condition the chief engineer or the manager will notice it and will demand more careful firing.

The reasons for the presence of unburned coal in the pit are too thin a fire, uneven firing, too frequent poking and slicing. The remedies are keep a thick body of fire on the grates, fire lightly and more frequently, in this way holes do not burn out in the fire and the freshly fired coal does not fall through the grates; also there is less tendency for the coal to form clinkers thus necessitating less poking, which of itself tends more than anything else to the formation of clinkers. If clinkers do not form the fires need cleaning less frequently thus saving a great deal of labor as well as coal. If the cleaning of the fires is not properly done considerable unburned coal is drawn from the furnace with the clinker and ashes. If after cleaning there is insufficient live fuel to cover the grates completely, some of the fresh coal will drop through to the ash pit. Before cleaning see that there is plenty of clean burning coal that can be left to cover the grates completely before building up the new fire. Fires should be cleaned as seldom as possible, as some coal is unavoidably thrown out with every cleaning. It should only be done when there is small or no load on the boilers. If heavy firing is commenced immediately after cleaning clinkers tend to form, while this tendency can be greatly overcome by building up the fires gradually with small and frequent firings.

A day's run should always be started with a freshly cleaned fire built gradually to full steaming capacity, and it will be found that fewer cleanings are necessary with fires operated in this way.

Before one can appreciate the losses due to the chimney gases, the principles underlying the combustion of fuel must be more or less understood. Since bituminous coal is the most commonly used fuel for steam purposes, we will direct

our attention to it only, although the general principles are the same for all fuels.

When coal is first thrown on a hot fire the immediate effect is to reduce the supply of heat going to the boiler, as this heat is used to heat up the fresh coal; thus if heavy firings are added it may interfere seriously with the constant supply of steam. As the fresh coal heats up, various combustible gases are driven off generally accompanied by pure carbon in the form of soot or dense black smoke. If the temperature is high enough and there is enough air present in the combustion chamber, these gases and the soot will burn, giving the bright flame seen over the bed of fuel. If insufficient air is present, only the more readily combustible gases will burn, leaving black smoke and other unburned gases to pass out the chimney. Unfortunately the heating value of the more readily combustible gases is much less than that of the other gases and when this condition occurs we are wasting the best part of the gaseous fuel. Some of the gases under these conditions are only partly burned forming a gas known as Carbon Monoxide, in the formation of which only a small part of the heat of total combustion is given off.

After the fuel has been on the fire a few minutes the gases are all driven off leaving coke which is a solid containing only pure carbon and ash. Since this coke burns in place on the grates there is now no necessity for air above the bed of fuel as there was when the gaseous products were being driven off.

Thus we see that we have two different conditions to deal with after each firing, as well as all the intermediate conditions. First we need air coming up through the grate bars to burn the coke on the grates, also we need air above the bed of fuel to burn the gases expelled from the coal. Gradually the combustible gas above the fuel becomes less thus requiring less air above the fuel until the gases are all burned and we need only sufficient air coming through the grate bars to complete the combustion of the coke.

In general a certain amount of air is admitted to the combustion chamber above the fuel bed through circular dampers in the fire doors. This rush of air also assists in keeping the fire doors cool thus preventing them burning. A certain amount of air is sure to leak in around the cracks in the setting, or between the boiler shell and setting, or around the fire doors.

In most hand fired plants it will be found that immediately after firing there is not nearly enough air above the grates, as only a limited amount will come up through the fire bed insufficient to burn both the coke and the gases and only a small amount leaks through the fire doors, etc. We thus get black smoke being discharged through the stack at intervals in most hand fired plants which shows incomplete combustion and consequently a waste of fuel. After the combustible gases have burned off, the same amount of air is still leaking around the doors, etc., but this extra air is not needed and does not help the combustion of the solid fuel. This air serves only to cool the products of combustion, thus passing cooler gases over the heating surfaces of the boiler from which less heat will be delivered to the water or steam. Thus we find a great waste in heating this extra air not needed for combustion.

These two conditions as described above can be more nearly equalized by frequent and light firing. In this manner there will not be a very great deal of combustible gas driven off at once and it will probably get enough air to more nearly complete the combustion, also by the time this gas is mostly all burned and the fire getting too much air it will be time for another firing, so that neither of the extreme conditions rise to serious proportions, nor do they last for great lengths of time. The ideal conditions are most nearly obtained in the constant feed types of mechanical stokers.

Success Electrically, Depends Upon Unity of Action

An Eloquent Exposition of the Essential Attitude of Mind, Alike in War and Peace, of a Progressive, Successful People

By Mr. A. Monro Grier, K. C.*

First of all permit me to congratulate you, sirs, upon having your convention held in what is now the historic Clifton Hotel. I had to do with the company which was the predecessor of the one now responsible for conducting this establishment, and I would like, as one who has passed from that, to pay my compliment to those who are responsible for it at the present time and to wish them, as doubtless you do with me, every success in their enterprise. Of course, in making that remark I impress in my thought at least, if not in my language, the actual meal we have eaten. I lay claim at times to certain spiritual tendencies, but I am not so spiritually minded as not to have a proper regard for the dictates of the stomach, and I must say I have enjoyed the meal, and have not found it, as I have found many other banquets, so meagre that I was glad to get home to get some nutriment.

I am reminded once more of that occasion when the Right Honorable Joseph Chamberlain was to speak at a certain dinner in England, and the mayor, presiding with rather more geniality than tact, said to the Right Honorable gentleman: "Will you begin now or shall I let them enjoy themselves a little longer."

Now I am getting started. I want to commence, if I may, by issuing a word of welcome to you all, and in case that should seem a very conceited utterance, since you are my hosts and I am your guest, let me say at once that I allude to the district of Niagara Falls, and it is not unbecoming that I should speak in the language of one welcoming you under the circumstances. For several years my interests have laid in Niagara Falls. In Toronto I have a legal interest. I have two lines of defence. If any man comes to me with a legal proposition and says "Look here, solve that," I say "My dear fellow, I am engaged in the electrical development work," and if an electrical man comes and says "I wish you would explain this technical difficulty," I say "My dear sir, I am a K. C."

I desire, as one connected with the company for a great many years, to extend a very hearty welcome. I do not use such a word as "Opposition Camp," but there have been different points of view by different bodies of men connected with the electrical industry in Ontario. I come to you to-night not as one in any sense hostile, but as one distinctly friendly and one whose attitude is that everything must be well, because it is always fair weather when good fellows get together.

It is not unbecoming on this occasion for me to mention that I have the honor of addressing you as president of the Niagara Power Company, and also as president of the Canadian Electrical Association, and in both capacities I bid you welcome. If in these official capacities that is my attitude, what shall I say of my own—individually? This: That if by any chance there lies in me any modicum or residuum of ill-feeling or a lack of friendship officially, there is not one iota of that from my individual standpoint, and as A. Monro Grier I bid you hearty welcome to Niagara Falls.

Now, you may perhaps be wondering what I am going to say to you to-night, and I have resolved my doubts to a certain extent, and so that I may not forget them all I

have noted them roughly on a piece of paper to which, with your permission, I will refer from time to time. It may be that some of you expect me to speak technically. That I shall not do. I have but one object, or perhaps two: First of all, speaking of you collectively, this, that your association may grow and prosper, and anything I to-night may say will help to its growth and prosperity and not retard it; that is of you collectively. Individually, my hope is this, that I, speaking as an older man to you all—certainly to most of you—may perchance say something which will be of assistance either in your business or in your private life. Not that I shall enquire into your official or private lives, but I shall hope that by reason of some years of reflection of life and its philosophy, something may have demonstrated itself to me as useful which I, in turn, may have the honor of passing on to you. And so I thought I would say something to you to-night in the way of inspiration. It has occurred to me that at this juncture in our country's history, and in the history of the world we must look for inspiration, for undoubtedly we have reached times that are hard and difficult from certain points of view. What inspiration can I communicate to you? You will be here for some days. What will you see when you are here? I charge you that you will get all the inspiration you should get from the works and wonders of Nature that you shall see. I am intolerant of the man who, coming to such a place as Niagara Falls, leaves it no wiser than when he came. It is the bounden duty of us all to gather something from the wonders around us and to enrich our lives therewith. What will you find, not alone in Niagara Falls, but also in the history largely of the world as written on the rocks which compose the boundaries of the river just below our seats? What may we not learn there as to the ages of the earth, and not only that, but of the patience of Nature in the things she accomplishes. What will you learn of all that has taken place between the time these falls rushed over the Queenston escarpment until by process of erosion they reached their present site. If you visit the Niagara Glen you will find now overgrown with trees, the veritable bottom of the river in an older age. And the lesson, as I conceive it, to be learned by all of us from regarding such matters as these, is something of the majesty of philosophy, the majesty of calm in storm, the majesty of repose when things are apparently against us, the majesty of patience in the working out of things not in a few passing moments or years, but down through the centuries. And if, perchance, at any time in your lives it may seem that things are not going as smoothly or as quickly as they should, that you are not reaching the goal before you as expeditiously as you desire, say to yourselves this,—and in so saying you will render me my greatest thanks—"On the 19th day of June, 1919, a speaker, laying no claim to merit as a speaker, yet suggesting that there was some merit in the thought, stated that you could have in matters of life such a splendid repose and patience as to make the passing ills of the day seem as nothing, and make you really bigger and better men." I really must be careful that I do not lay myself open to the charge of having uttered a lay sermon. Please understand that I am not doing anything of the sort. I am speaking to you from a lower plane, or certainly one no higher than your own. I am speaking to you as one man to others, and uttering a few

*President Canadian Niagara Power Company; president Canadian Electrical Association, before Niagara Falls Convention of Ontario Municipal Electrical Engineers.

passing thoughts which conceivably will be of use and interest to you.

Now, what do you see here of the works of man, the completed work of electrical development? As I have played for eighteen years a part of some importance in that development, it is obviously of good taste that I say nothing about it. I only suggest that it is perhaps a matter of inspiration to you to see what has been accomplished already in the harnessing of Niagara. I understand that on Saturday you will visit the work now in progress between Chippewa and Queenston, and I have no doubt you will marvel with me at the size of the undertaking and the magnitude of the conception of the plan, and speculate as to its final result. But I will not keep you with details as to that. I daresay in any event that each and all of you are better able to judge of such a matter than I am, but I make this remark, that as representing the interests I do I have no attitude of hostility towards anything that is for the good of the province or the country, but am absolutely in favor of everything that is for the real benefit of the province or of the country at large.

Now, I am going to speak of another inspiration which is not of to-day, but certainly was of yesterday, and, in a sense, is still of to-day, because only an armistice, and not a peace, has been signed. If you say to me: "we have heard enough of the war," I say to you: "in certain ways we can never hear enough of the war." I am not going to give you a history of the matter. I simply let you know my purpose in advance, so that if I fail you may see how greatly I fail. I suggest this thought to you, that the old adage of "unity is strength" is being fulfilled over and over again, and perhaps in this country has been fulfilled more than ever before in the history of the world, and that in this thought there lies a truth that the duty of man is to do his own work, and if we do our own work and recognize the value of unity there is no question of the future success of this or any other association. What shall we choose from the war from which to derive inspiration? I point out to you the unity of the empire itself. You remember the time when Germany, amongst the idiotic things she did think, thought that the "colonies," as they were called, would not come to the aid of the old country. Fool! What happened? Before the official declaration of war had been made Canada offered her aid to England in the great war for freedom and the liberty of man. And they trooped from everywhere, from Australia, New Zealand, Africa, from the uttermost parts of the earth, and the outlying parts of the empire, including the Boer chief and others under him! Mark the difference! In 1870, forty-four years before this present war broke out, Germany had conquered Alsace-Lorraine, and yet, in 1914, there was a bitterness and a hostility towards Germany, on the part of the Alsations, that nearly half a century had failed to eliminate. In the case of the Boers, however, with whom England had been at war just a few short years before, what did we find? They allied themselves with the old country and their attitude was one of comradeship, of friendship. In truth, the fact is that these bonds which bind the various portions of the empire together, which are so thin you cannot touch, you cannot handle, you cannot see; these things which are so fine materially, spiritually are so strong that not the steel of the greatest strength can by any possibility attain to their coherence.

We had a unity not only amongst the nations composing the Empire, but amongst the several branches of the service, and I want to allude to this here because I understand that members of this association and their relatives went overseas. In fact, there is no household in Canada or any part of the British Empire to-day that has not had some association, through their relatives, with this war. And just

for a moment let us see the extraordinary unity that prevailed amongst all ranks and all branches of the service. The army fought cheerfully with the navy, and both cheerfully with the air service, and with them all co-operated the women of the empire in their several places, all with one object in view—absolute unity. It mattered not one whit what was the religion of any man, how high he was amongst the officers, or how low he was in the ranks, all were the same, whether in the army, the navy, the air force, or elsewhere. And not only were the official soldiers and sailors fighting, but we had that tremendous navy of fishermen who, hitherto devoted to peaceful pursuits, abandoned them in order that they might carry on for the Empire and for freedom, all showing the marvel and beauty of unity. Can you imagine any finer situation amongst the Allies than their voluntary subordination to that magnificent French officer, General Foch? Careless of their own particular standing, all united under him in order to win the battle.

Then, look at the wonderful co-operation in the navy. You remember how the American navy went forward and co-operated with the British navy, the officers and men subordinating themselves to the ranking British Admiral. Why? Because they were not concerned with showing their own individual exploits, but with proving to the world that the Hun was an abominable beast and that Germany could not rule the world and that freedom must.

Now, let us glance at our own problems, and ascertain, if we can, what is best for us in these trying times. Peace and good-will was that splendid message of old, and peace, I trust, we shall shortly have, and now to get the good-will! That is really the important thing in all our activities in life. If you get enough men of good-will banded together they can accomplish anything for good. For myself, though I admit my obscurity, I do claim I have good-will, and if I meet any man, I care not of what rank, or camp, or association or interest he is, provided always he is a man of good-will, I shake hands heartily and wish him God speed in any venture he has for good. And this should be the attitude of us all. Your action to-night demonstrates that it is possible to have one from another interest speak to you in a voice not unfriendly, but in such a way as to suggest that he was one of yourselves. So I charge you to give me the thanks of bearing in mind just the outlines of what I have said. Please remember more than ever the vast wonder and splendour of unity. Sometimes when I walk into a great powerhouse and contemplate the majesty of a generator (which is obvious to you) and think of the little things in the wheel-pit (which I and some of us present know about) I reflect on how we all see the things of splendour and ignore the humbler. Yet the generator is dependent on the little things in the wheel-pit, and were the small things in the wheel-pit to say "I shall no longer act as a wheel bolt or nut, but would rather be a generator," and attempt to carry out its desire, it would show it was an uncommonly bad nut or bolt—that is something we have to learn.

Contemplate for a moment such a majestic character as Abraham Lincoln. Some people have the notion that the great point of his life is to demonstrate that a man of obscure beginnings can become President of the United States. That, perhaps, incidentally is taught, but it is not the main lesson. The main lesson of his life is that whether a farmer or an obscure lawyer in a western town, in each and every position we must do our duty, and it is on that account that after the lapse of so many years the world still rings with the applause of that tremendous, splendid man.

I am very much concerned about getting this simple lay message directly into your consciousness, but I daresay you feel it is quite time I concluded, and I think so too, and I am going to obey the injunction of someone who said to a

man who did a great deal of public speaking. "When you have finished sit down quietly lest you awake the sleepers." Just bear that thought in mind as to each doing his duty. May I give you an illustration as to unity? Perhaps you have heard this before, but it is worth hearing again. Do you ever have in your mind what is causing this light to shine, these electric street cars to run, these electro-chemical places over the river to do the wonderful work they do? May I give you an illustration as to unity? Perhaps you played a greater and more significant part in the war than Niagara Falls, because we were sending such a tremendous amount of stuff to Europe for the allied armies). Why is Toronto and all of the province engaged in vast manufactures? Simply because a certain number of individual drops of water are falling down a certain given space. That is the whole thing. I ask you to consider what would be the effect if you drop one drop of water to-day and another drop to-morrow and another the next day. Absolutely no effect. The effect is wholly produced by means of unity. By the drops falling down together, and in that we get probably the most majestic conception of man's handiwork to be found in the civilized world.

In conclusion, let me quote Tennyson's beautiful lines written to the late Queen Victoria during her reign, and let me suggest that we apply the spirit of the language to our own councils and thus secure better results:

"And statesmen at her council met
Who knew the seasons when to take
Occasion by the hand, and make
The bounds of freedom wider yet.

"By shaping some august decree,
Which kept her throne unshaken still,
Broad-based upon her people's will,
And compass'd by the inviolate sea."

Efficiency Engineering in the Electrical Industry

Capital Cost of Improvements Saved in Two Months' Operation

By Mr. A. L. Mudge*

The following are typical examples of improvements in electric light and power systems in large industrial establishments, and indicate the possibilities of what may be accomplished in many other cases.

I. Reduced Power Bill \$3,000 per Annum

A manufacturer using about 400 h.p. was penalized by the power company on account of low power-factor. The power consumption of every motor in the plant was tested and many motors were found to be too large. Several motors were loaded to less than 20 per cent. of their rated capacity. Drives were re-arranged, four motors released—and sold for more than enough to pay total cost of changes, and annual power bill was reduced by \$3,000.00. Further, a goodly portion of the power company's stations, transformers, and lines was released to carry other important war demands for power at a time when such capacity was very badly needed.

II. Two Months' Savings Paid Capital Cost.

A manufacturer in Toronto with motor installation of 3000 h.p. was using about 1400 h.p. supplied from sub-station three-quarters of a mile away at 550 volts. Due to war conditions, load had grown very rapidly till there was a loss of about 400 h.p. in line and an excessive voltage drop frequently to below 450 volts, as shown by the inner curves in the accompanying chart.

This caused the following conditions in factory:

1. Motors would overload and heat excessively, making it necessary to shut down for cooling and repairs.
2. Motor fuses would blow and shut down motors.
3. Main circuit breaker would open and shut down entire factory one or more times a day, leaving 1,500 men idle.
4. Motor load going off caused excessive voltage rise. In one day this resulted in burning out \$64.00 worth of lamps.
5. The switching arrangements at the centre of distribution were also very inadequate and dangerous.

The work done consisted of:

1. Examining entire electric power system of factory making tests of power consumption, power-factor, etc.
2. Making analysis of power bills and operating conditions.
3. Negotiations of new contract with power company.
4. Design and construction of 2,000 h.p. sub-station at factory, to which, under the new contract, power company delivered power at 12,000 volts. The power company was able to loan transformers to the manufacturer on account of transformer capacity released due to the changes.
5. Purchase and installation of new 8-panel distributing switchboard.
6. All change-overs were made during usual week-end and holiday shut downs, causing no interruption to production.

The results obtained were:

1. Continuous service at steady normal voltage; see outer curve in the accompanying figure. This means the elimination of all the trouble referred to above, and gave an

Voltage curves—Inner, unregulated; outer, higher and better regulated

increased production of many thousands of dollars per month. It is interesting to note that with an average closely regulated voltage of 600 at sub-station, instead of 500 volts badly regulated, motor speeds will be 2 per cent. higher, giving both increased production and better quality of work on account of higher and steadier speed.

2. Safe and satisfactory handling of load through new switchboard with ample provision for extensions in future.
3. Entire capital construction cost comparatively small, being less than amount of the savings which resulted during the first two months following change-over.
4. Practically all of the 400 h.p. line loss was released for use elsewhere when war demand for power was very heavy

*Consulting Engineer with Kerry & Chace, Limited, Toronto.

The Contractor-Dealer

Declaration of Principles to Guide Electrical Contractor-Dealers

The members of the National Electrical Contractors Association in their Milwaukee Convention approved a "Declaration of Principles," as follows, which recognizes the necessity of establishing closer working relationship between the various elements in the electrical trade, and between employer and employee in that trade:

Principles

1. The facilities of the electrical industry for service to the public will be developed and enhanced by recognizing that the overlapping of the functions of the various groups in the industry is wasteful and should be eliminated.

2. Close contact and a mutually sympathetic interest between employee and employer will develop a better working system, which will tend constantly to stimulate production, while improving the relationship between employee, employer and the community.

3. Strikes and lock-outs are detrimental to the interests, alike of employee, employer and the public and should be avoided.

4. Agreements or understandings which are designed to obstruct directly or indirectly the free development of trade, or to secure to special groups special privileges and advantages, are subversive of the public interest and cancel the doctrine of equality of rights and opportunity, and should be condemned.

5. The public interest is conserved, hazard to life and property is reduced, and standards of work are improved by fixing an adequate minimum of qualifications in knowledge and experience as a requirement precedent to the right of an individual to engage in the electrical construction industry, and by the rigid inspection of electrical work, old and new.

6. Public welfare, as well as the interest of the trade demands that electrical work be done by the electrical industry.

7. Co-operation between employee and employer acquires constructive power, as both employees and employers become more completely organized.

8. The right of employees and employers in local groups to establish local wage scales and local working rules is recognized, and nothing herein is to be construed as infringing that right.

Two Dollars or Six Dollars per Outlet?—Cost of Wiring Old Houses Always Uncertain

Some interesting figures were recently gathered by the Housing Committee of the National Association of Electrical Contractors covering the cost of old house wiring. Eighty-four replies were received from the questionnaire sent out from which it appears that the cost ranges from \$2 per outlet to \$5.25 per outlet. In a recent job in Toronto the net cost ran approximately \$6 per outlet, including service for an electric range. The figure of \$6 was worked out with painstaking care and accuracy and demonstrates beyond question that the contractors who figure at \$2 or \$3 an outlet have no chance in the world of making a decent living.

The biggest factor of uncertainty is labor. You never can do more than guess before hand what obstacles will be met. It is all the more necessary then that you have accurate data on part work.

In commenting upon the situation the Committee remark that "Many contractors have no systematic method of estimating house wiring; either a back of an envelope or a business card is considered sufficient for estimating any job. The committee recommended unit price estimating on a form which gives sufficient space to properly note each room, outlet, switch, plug, etc., and allows less opportunity for omitting necessary parts of the estimate, which usually results in a loss to the contractor dealer.

"Your committee further recommends that not less than 50 per cent. profit be added to the net cost of labor and material on any house-wiring installation below \$300 for the reason that the overhead on this class of work is higher than store, industrial lighting or power installations. The average time required to wire a three-storey house will take from five to fifteen days; the cost of the material is about 40 per cent. of the total cost of the work, labor representing the balance, so that the time necessary to install this class of work is of such duration that it is necessary to charge a larger percentage of profit to cover the increased overhead.

"In all house wiring jobs the committee suggests that only the best materials be used, and recommends to the owners that switches add to the convenience of the installation and should be placed for any important room. Do not place the control of electricity in the same class as the old-fashioned gas jet. And now regarding outlets; study the requirements of each room and suggest to the customers the advantage of having a number of these outlets placed throughout the house; the average customer having electricity installed for the first time, is not familiar with these conveniences, and the contractor-dealer is the one to urge the installation of the same.

"The committee further recommend that the contractor-dealer advertise more freely, and conduct intensive campaigns, during the spring and fall, to be followed up by active solicitation at all times."

Selling "Sight Unseen"

Here is a plan which a dealer in a small California city has found effective as a means of keeping trade from going to mail order houses.

When he started to sell Westinghouse irons one of the first things he did was to order a \$5.50 "mail order" iron.

In due time the box containing the iron arrived. The dealer, however, did not open it. Not a string was untied or a seal broken, and the box was left on the counter near his own stock of irons. When customers began dickering over the prices of the Westinghouse iron and mentioned, in contrast, the price of the mail order iron, he was ready for them.

"Why," asked one lady, "should I pay you \$7.00 for an iron when I can send east and get a Stands Anywhere iron for \$5.50?"

"Oh, you want the 'Stands Anywhere' iron, do you?"

responded the dealer. "Well, I carry that, too. I'll be glad to sell it to you."

"Where is it? Let's have a look at it," answered the lady.

"It's right there in that box," said the dealer.

"Open it up. Let me see whether I want it or not."

"No," said the dealer. "It will stay in that box 'til it's sold. Isn't that exactly the way you buy from the mail order houses? Don't you pay your money before you ever open the box? I'll sell the iron to you on the same terms. That's fair, isn't it?"

The prospect saw the point. This incident has happened a good many times since. The box is still unopened. But it has proved as profitable an investment as the merchant has made in a long time.—Electrical Contractor Dealer.

Northern Electric Power & Light Sales Convention

A very successful convention of Northern Electric power and light dealers for western Ontario was held at the Tecumseh Hotel, London, August 12th and 13th. This convention was attended by over twenty dealers and their representatives. Afternoon and evening sessions were held on Tuesday, and forenoon session on Wednesday. On Wednesday afternoon the dealers inspected the Northern

The company markets through its dealers a broad range of accessories to lighten labor on the farm. Mr. C. L. McMullin, sales manager of the Fuller-Johnston Engine Company, of Madison, Wis., gave a very interesting and instructive talk on gasoline engines. The Fuller-Johnston model "K" engine, which the Northern Electric Company has adopted for use with their belted type plants, has been specially designed for this purpose and has proven reliable for such service. The dealers and representatives of the different manufacturers and of the Northern Electric Company dined together in the evening at the Tecumseh House.

After dinner Mr. J. Astram, of the Fort Wayne Engineering & Mfg. Co., Fort Wayne, Indiana, gave a most instructive talk on the well-known line of Paul pumps which are being distributed throughout Canada by the Northern Electric Company. Mr. D. M. Simpson, manager of the Chicago office of the General Lead Batteries Company, described the theory, operation and care of storage batteries, accompanied by lantern slides. This talk was presented in such a way that the dealers realized that storage batteries are not so mysterious as is generally conceded.

On Wednesday morning Mr. Campbell presented a very interesting paper, "Northern Electric Company and the Dealer." Some interesting extracts from this paper were published in our last issue. After Mr. Campbell's paper,

Flooding the country-side with power and light. Northern Electric Co.'s agents in convention at London, Ont.

Electric Company's London branch and a photograph was taken of the delegates.

Mr. B. L. Baulch, manager of the London branch, welcomed the delegates to London and explained the object of the convention. Mr. T. R. Campbell, power and light sales specialist, from the company's head office at Montreal, outlined the line of power and light plants and accessories which the company is marketing through its dealer organization. He answered a number of questions relating to the operation of the different plants and devices. Mr. G. H. Nablo, of the Matthews Engineering Company, Sandusky, Ohio, outlined the policy of his company and gave some very interesting details regarding the different types of automatic, semi-automatic and hand-controlled plants which they manufacture at their factory. Mr. Nablo also described briefly what his company had done to supply the U. S. Shipping Board with 6 kw. automatic plants for use on transports, for emergency lighting, and to supply current for wireless in case the main power plant should be put out of operation. Mr. P. O. Roberts, power and light specialist of the Montreal office, read a paper prepared by Mr. T. N. White, sales engineer and manager of service department, on "Service and Installation." This paper outlined the company's policy on service, which is very comprehensive. A paper was also read by Mr. W. P. Tice, of the company's accessory sales department, on the subject of accessories for use with Northern Electric power and light plants.

over an hour was spent in open discussion of points of interest to the dealers. Many interesting experiences were related by different dealers and suggestions exchanged which will assist in the sale of power and light equipment. Mr. McMullin gave a very live talk on "Selling the Farmer," which abounded with interesting anecdotes and experiences. Many suggestions were offered as to how a dealer could more intelligently present his proposition to the farmer prospect. Mr. J. A. McDonald, power and light specialist in Toronto office, acted as chairman throughout the sessions.

Representatives of the manufacturers and of the Northern Electric Company were very optimistic of future sales and the dealers shared in this and were very enthusiastic over Northern Electric Power & Light. The dealers expressed themselves as being thoroughly convinced that they were doing their customers a service by introducing the most up-to-date and reliable equipment available. The enviable reputation enjoyed by this company in Canada assured for the dealer and his customers reliable equipment and real service.

Run a slogan in your advertising at least once a month, something like this: "Buy your electrical goods at an electrical shop." Do not let the hardware and drug stores get away with the business which rightfully belongs to you. Put up a fight that will win out.

Sale of Electrical Labor Saving Devices to the Farmer

By Mr. W. P. Tice

The first thought that occurs to the writer is, will the idea of appliances come first or last, and while it is true that the apparatus to produce the current supplying the appliances must necessarily come first, one must have a thorough knowledge of the appliance situation, as it is as necessary as the study of the apparatus itself, for its conclusion is the installation of the appliances, they always come no matter what the first plans are, for they are the real life and essence of the power and light installation, and without them it would be like a cart without a horse. So never worry about the sale of appliances—**put them in, send the bill, they sell themselves.**

Do you really know the farmer? If not, go out and get acquainted, and especially so the women folks, for no other class are as consistent and long-hour workers as they are, and also with the fewest helpful devices. Did you ever have the opportunity to study the women on the farm during her daily tasks? If not, do so, and you will have all the necessary sales helps to sell them the useful appliances that they require, and when you have sold the farmer the useful and labor-saving devices, you have accomplished a real service. As previously stated, study the farmer, and it will be an interesting study too, for he is a different type of man than you have come in contact with, and one that requires a different class of salesmanship than you have before met with. He has not had the years of training and demonstration in the electrical lines his city brother has, and the field is very fertile, but do not make the mistake of trying to impress him with your greatness, but talk to him as man to man, for he is not interested in sales rhetoric. Show him, for he certainly is the answer to the common expression "I am from Missouri." Impress upon him the many advantages of a water system, for it is one of the most important appliances on a farm, and constitutes the greatest of labor-saving devices to him. Assuming that the light installation is the primary feature which seems to be the case, although I do not see why, and after it the water system, then what do you think naturally comes next? Why, the devices that will lighten the labor of the wife, for it is a known fact that the farmer is more considerate of his own women-folks than is the city man, and will put in an iron and washing machine quicker than a feed grinder, if the value is shown him first. Settle the women part first, then you can go to work and install a separator, churn, grinder, milking machine, sheep shearer or clipper and the many other useful and labor-saving devices that are now on the market.

You will find that, due to the rapid progress made in power and light equipment, it will hustle you to keep up with the development of new devices being manufactured from time to time. There has been much written upon the proper methods of approaching the farm prospect, some of which are very good, but I honestly feel that personality and good, clean-cut, right-on-the-farm demonstration, is by far the most successful. I do not think it necessary for me to go into detail with each piece of apparatus, as the manufacturer of appliances has done so very thoroughly, and his literature will be of good help to you to sell successfully. You must know the device cover to cover, and if you do not, make it a point to take each and every device to pieces, and study it carefully, and learn how it operates, how it is put together and its purposes, for no one can be a successful farmer salesman unless he does know all about the device he is selling, for you know the farmer is from "Missouri". He never has had a machine or a repair department

to run to, like his city brother, and has had to take his machinery to pieces to see how the darn thing works, and has had to make his own repairs, so you will find him a far better mechanic than is commonly supposed, so don't let him have to show you how the wheels go round. You will impress him more if you can show him, for he knows that all mechanical contrivances, at some time or other, need repairing, and he wants to know the whyfor.

This was supposed to be a talk on how to sell the farmer labor-saving devices, and I am afraid I have considerably transgressed the subject, but it is not the same kind of selling one would meet with in the contractor-dealer or city customer, and requires different methods, principally personality and a thorough study of the needs of the farmer. Nickel-plated and gold trimmings have ceased to exist to him, as has the gold brick.

Many estimates have been made of the number of power and light prospects, which I am not in a position to deny or confirm, but such being the case, a glance shows what an enormous volume of appliances are to be sold to keep up with the estimates, and you, Mr. Dealer, are the logical one to sell them, and they all carry a well worth-while profit, and then, too, they are a never-ending source of profit, as they continue to increase in numbers, and as is the case with lamps, they continue to be always in demand. The sales prospects are as bright as the sewing machine salesman's slogan, "Every bride a prospect, and never worry 'till the marriage rate declines."

What are Your Sales Plans?

By Mr. Sydney Neu

The old-time business man trusted to luck. If business was good it was good. If it was bad, too bad, he must make the best of it.

The modern business man believes in initiative. He believes that business is never so good that he cannot improve it by effort. And by this initiative he has moved the old-timers to the side streets and the back alleys where they gradually drop out of the running. He plans and executes.

Before you can plan you must know. You must know what your sales were last year, not only in total but in each individual line. You must know what stocks you carried, not only in total but in each line so that you can figure your turnover. You must know what your expenses were and how much of this expense was caused by each line. If you do not know these things the first step is to find them out.

The next step is to analyze what you know. This line required a large stock and moved slowly; was this a fault of the line or because you did not display it and push it? This line sold so fast that you lost sales through insufficient stock. This line had a big mark up but it took so much clerks' time to sell it that it probably made you little money.

After you have digested the facts you can plan. You will throw out this line entirely. You will push this line hard and double your sales. This line you will keep constantly in your show window and expect sales to increase to three times. And so on.

But plans are not enough. The plans must be put into action and kept going. They must be checked up frequently. If sales in any line are not up to the mark you have set, you know it is time to concentrate your advertising and display and sales clerks on that line.

Plans and records are essential to any business success. The best use you can make of your own time is in making plans, watching the records, and keeping things moving faster. Leave the mechanical work to those whose time is less valuable.

Complete Electrical Equipment for the Home

By Mr John G. Learned*

There exists a community of interest among electrical manufacturers—jobbers—dealers—contractors and central stations in the fostering of the complete electrical equipment of the home,—therefore, the plan of the National Electric Light Association—Commercial Section, to bring about a nation-wide educational campaign for the purpose of creating a greater demand for complete installations of wiring and appliances in the home will meet with your favorable consideration.

Although the electrical industry has made most remarkable strides in the last 25 years we have been woefully deficient in focusing our efforts on educating the public to the unit idea of electrical equipment in the home. Electric lighting installations are fairly well handled, although there is vast room for improvement, whereas the necessity of an adequate number of outlets for the use of portable and electrical appliances has been sadly neglected—by comparison. The future permanent success of the "Residence Service" branch of our business depends largely on our ability to so thoroughly educate the public that the lay man and lay woman will be as conversant with the complete unit electrical equipment of the home as they are now with the electric starter, the electric headlight, the electric horn and the other refinements of the automobile. There never was a more opportune time than now—especially on account of the present shortage of household help.

The Commercial Section of the N. E. L. A. plans to get the manufacturers of electrical heating appliances, washing machines, vacuum cleaners, portable lamps, fans, vibrators, hair dryers, sewing machines, etc., accessories and other appurtenances used in the home, to include in their national advertising **an illustration of the baseboard or wainscoting receptacle**; the idea being to show the particular appliance advertised and the cord connecting it to a receptacle. This can be done without any additional expense. Those manufacturers, who have had this matter brought to their attention are very enthusiastic and have already taken steps to co-operate.

Central station companies are having this matter brought to their attention, and are being urged to feature appliance outlets along the same lines in local newspaper advertising—on billboards—customer's bills—and salesroom advertising. Department stores will be urged to follow suit. Jobbers, dealers and contractors should get behind this campaign—which is not for a week or a month but continually—the results will be cumulative.

Another method of bringing the message home is to make up window displays of appliances with their cords connected to receptacles mounted on section of baseboard or wainscoting.

Special attractive advertising in pamphlet form on this subject of receptacles will be prepared for distribution to architects by central stations.

Below I quote the advertising manager for a manufacturer who is particularly enthusiastic on the subject:

"One way to increase the interest and, therefore the installation of more adequate provision for use of electrical appliances in the home, is to form a small committee to outline a complete campaign to cover a given period of months. Some of the things to be done are as follows:

(1) Prepare cuts of several sizes and kinds to be furnish-

ed to all manufacturers of electrical goods and to have these cuts used similarly to the Bond and War Savings Stamp will therefore act as constant reminders to all of us in the electrical industry and those cuts used in the national media by the various manufacturers who advertise in such publications will help to bring home this campaign to the public in general.

The cuts mentioned above can also be used in the various folders, literature and on letter-heads, during this same period regardless of what the folders or other literature describe.

(2) Special Folders and Other Printed Matter

Folders and other small pieces of printed matter to be prepared specially on this subject of the advantages of more adequate equipment for the use of electrical appliances, and this material used as envelope stuffers by lighting companies, manufacturers and their district offices, engineers, electrical jobbers and electrical contractors and dealers. A good portion of these stuffers would therefore, reach the hands of the public also.

(3) Small Stickers for Letter-heads

A series of these could be prepared covering the subject which could be used over a period specified in the campaign by the same group mentioned above. Many of these would come to the eyes of those interested in building.

(4) Manufacturers making devices which would be consumed in installing adequate equipment in the home, would be urged to extend their advertising and concentrate on devices such as receptacles, etc., during the period decided upon for this campaign. These same manufacturers will furnish to the dealers, contractors, and lighting companies, small electros and other suggestions, advertisements, and folders, which could also be used for local and newspaper advertising by the contractors and dealers and electric lighting companies.

(5) Little stories, articles, and illustrations could be prepared for the various electrical journals as well as some specially prepared for the general publications such as Good Housekeeping, Woman's Home Companion, Ladies Home Journal, House and Garden, etc.

I am sure we can get in touch with the persons preparing these articles for such magazines and have the need for adequate outlet equipment emphasized in these articles and possibly, have at least one article devoted to that one subject alone.

(6) Electric lighting companies during this period could also be instructed on attaching slips to the electric lighting bills, slips giving a message concerning the conveniences of more adequate wiring of the home.

(7) At the same time, the architects and electrical contractors figuring on wiring jobs should be urged to bring the matter of convenient outlets to the builders' attention, since a good many people still are not familiar enough with electrical work to appreciate the wonderful convenience of having many outlets, as for instance in the baseboard and do not realize that the addition to these outlets does not mean very much greater cost when figured over a period of say five to ten years.

(8) Short Movie Films and Slides

There are a number of companies prepared to make up movie films which are produced in such a satisfactory manner that the moving picture houses throughout the country are glad to make use of them in connection with their usual program. In such films, a very forceful appeal can be made and the convenience of many outlets can be played up in a pleasant though distinct manner and the disadvantages of a poorly equipped home emphasized. The mind of the theatre-goer is in a particularly receptive state when looking at the

*Before Milwaukee Convention National Association Electrical Contractors and Dealers.

screen and such films in connection with other slides advertising the installation of various receptacles by local contractors and lighting companies will tie up very strongly with the other promotion work noted above.

(9) The subject matter for advertisements might play up the saving in wear on electrical fixtures; the great convenience of electrical appliances is made still greater by the provision of adequate outlets or attaching places for the ready connection of electrical appliances in various rooms, to electrical circuits; safety could be emphasized also.

(10) Various little stickers for use on letter-heads might have subjects similar to the following:

"When Wiring Your Home Have Outlets Arranged for Your Electrical Appliances."

"Double Electrical Conveniences—Have Extra Outlets for Electrical Appliances."

"Save the Wear on Electric Fixtures—Connect Your Electrical Appliances to Baseboard Outlets."

"Have Extra Outlets in your Laundry as Well as in Your Living Rooms for Your Electrical Appliances."

"Electricity is Your Servant—Have Outlets Installed for Your Electrical Appliances."

These ideas are formed only in part but they serve as a starting point and could be developed into more complete form and augmented after a little conference on the subject. With any kind of work it is easier to have some actual start than to just talk the matter over.

Slogans and Text Matter

Follows some ideas intended to suggest slogans and text matter which might be further developed in detail for use in support of a campaign for more electrical outlets.

(1) "Let out pent up Electric Service by installing more outlets."

(2) "Electrical outlets increase house values. Provide one or more extra outlets in the floor, baseboard or wall in every room for the convenient use of Electrical Appliances and Portable Lamps."

(3) "Modernize the (your) home with extra outlets for the use of Electrical Appliances."

(4) "Take full advantage of Electric Service. Install extra outlets in every room for the use of Time and Labor-Saving devices—Electrical Appliances."

(5) "Extra outlets for Electric Portable Lamps—for utility and beauty."

(6) "Advocate Installation of Extra Electrical Outlets—for Appliances and Lamps."

(7) "Extra outlets promote sale and use of Electrical Appliances and Lamps."

(8) "Campaign for more Electrical Outlets."

(9) "Insufficiency of Outlets Restricts use of Electric Service. Increase sales of Electrical Appliances and Lamps. Install one or more outlets in every room of every home."

(10) "In wiring old houses install generously well-located electrical outlets."

(11) "Provide Complete Electrical Installations in New Houses—especially outlets for Appliances and Lamps."

(12) "Numerous faucets are provided in the home for the convenient use of water. Why not more outlets for the use of Electrical Appliances and Lamps?"

(13) "More outlets for More business."

(14) "More Electrical outlets—more Satisfied Customers."

(15) "Extend Electric Service by installing more Outlets."

(16) "Don't rob Peter to pay Paul. Install more outlets for the simultaneous use of Electrical Appliances as well as Electric Lighting."

(17) "The Modern Home Uses Electric Service. Extra

Outlets in each room for the convenient use of Electric Appliances Solves the Servant Problem."

(18) "For quick, convenient use of the Electric Heating Pad provide an extra outlet in Your Bedroom."

(Note: Series of such phrases—to apply to all Electrical Appliances and Lamps for all applications—can be developed for use by manufacturers, etc.)

(19) "For Complete Electric Service in Your Home Install Extra Outlets in Every Room. Use Electrical Appliances and Portable Lamps."

(20) "In nearly every house nowadays some provision is made for the use of electricity, but very often too few outlets are installed for the convenient use of Electrical Appliances and Portable Lamps. To rectify such omission after house is built is expensive.

Moral: Make your Electrical installation complete at first. Install extra outlets in every room."

(21) "Electric time and labor-saving appliances have become a necessity in the modern household. Provide for their convenient use by installing extra outlets in every room."

(22) "Electricity will increase the value of your property many times over the small cost of your investment. Be sure your installation is complete. Install one or more extra outlets in every room for the use of Electrical Appliances and Portable Lamps."

(23) "Mr. Business Man—You use several telephones in your office for good business reasons; also for convenience. How about your home? Extra outlets in each room permit the convenient use of time and labor-saving devices—Electrical Appliances Give a Thought to the Wife. Install more electrical outlets."

(24) "For Comfort, Convenience and Economy Install Extra Outlets for Electrical Appliances and Portable Lamps."

(25) "In planning your home provide for modern plumbing, adequate heating and complete electrical equipment. Be sure to install extra outlets in each room for Electrical Appliances and Portable Lamps."

(26) "Do a good job while you are about it. Don't skimp on Electrical outlets."

(27) "You buy furniture, rugs and decorations to make your home 'comfy' and artistic. Electric Portable Lamps enhance the whole. Install extra outlets for their use."

(28) "Baseboard outlets or outlets on the side walls which make it unnecessary to stoop down when attaching Electrical Appliances, should be installed in every room in your home."

(29) "An extra outlet or two installed on the porch will be found useful for attaching the Electric Fan or Portable Lamp."

(30) "Install outlets in the halls for use of the Electric Vacuum Cleaner."

(31) "It is modern to 'Do it Electrically.' Install necessary outlets in every room for the use of Electric Appliances and Portable Lamps."

(32) "The Completely Electrified Home Will Remain Modern for Years to Come. Install Plenty of Outlets."

(33) "Electrically Operated Pianos and Phonographs are popular. Provide for their use. Install Extra Outlets."

(Note: Makers of such equipment might be induced to co-operate in the campaign for more outlets—help them as well as the electrical industry).

It follows as a matter of course that if this work is taken up in a big way as outlined that the public will be educated to the necessary degree with the result that a big demand will be created for wiring, receptacles and appliances.

The contractors will do more wiring, the dealers will sell more appliances, the jobber will do more business—the manufacturers will turn out a larger volume of products—the central station will enjoy more revenue and last but not least the consumer will enjoy complete residence service.

Report of House Wiring Committee of the National Association of Electrical Contractor-Dealers

The duties of this Committee, as outlined in the organization plan of the National Association of Electrical Dealers is referred to as follows:

"To investigate and develop data and circulate information regarding methods of securing and cost of installing electrical materials."

As the Minutes of our Association do not show that any previous report has been made on the work of this committee, this must therefore be considered as the first report and recommendation of the House Wiring Committee.

In the past and particularly to-day, the wiring of old and new houses has been and is an important and large part of the total business of the greater number of electrical contractor-dealers. The majority of new houses now in course of construction are already wired for electricity, so that this class of business comes to the contractor dealer without any effort on his part to secure the same, but it is the many old houses that offer the greatest opportunity to the contractor-dealer, who will actively solicit this business in an intelligent manner, and from the following figures it must be assumed that old house wiring is a large part of the total business of the majority of our members.

The last report of our General Manager shows 1,613 classified members. Of this number, 603 are in class "A" doing business up to \$12,000; 343 are in Class "B," \$12,000 to \$25,000; 393 in Class "C," \$25,000 to \$50,000; and the balance, 274, doing business above \$50,000, making approximately 83 per cent., or a total of 1,339 members doing business of less than \$50,000 yearly, to whom the house wiring business must appeal, and to the balance of our members as well, if the work could be secured on a profitable basis.

The present data available shows that in the United States to-day, a very small percentage of the houses are wired, and this business offers an all year opportunity to the contractor-dealers to secure this work as well as the many appliances, fixtures, etc., that must follow the installation of the wiring.

The field is more fertile to-day than ever before. All war restrictions have been removed, the central stations are in a better and stronger position to supply the energy and extensions, and the "Buy Your Home Movement," which is being so widely exploited by the Department of Labor, makes the general public realize that every man is entitled to live in a comfortable home with cheerful surroundings and modern conveniences, and certainly electricity offers the greatest opportunity to increase the comforts of the home.

So that the Committee could be better informed as to the actual conditions existing throughout the country, and to secure data that would show in a general way what plans contractor-dealers have put into operation for securing old house wiring, a questionnaire was mailed to every member, a copy of which is made a part of this report, and the following is an abstract of the answers received:

Total replies	84
Number of States	26
Number of Cities	60

The number of contractors answering this questionnaire composes a very small percentage of our membership, and it would seem that a larger number would be sufficiently interested in this subject to answer the questions noted therein.

A sufficient number of States and cities have been heard

from, however, so that it has been possible for your Committee to secure information covering the entire country, even though a number of States are not represented.

The replies to questions are given in general terms as follows:

Fifty-three cities report that local central stations are co-operating with the contractors, and house wiring contracts are secured by the central stations and turned over to the contractor dealers either on a unit price basis or lump sum contract.

Ten cities report that the electric light company execute the work with their own wiring department.

Twenty-seven cities report that the contractor-dealers advertise for house wiring, and the same number have solicitors.

Forty-eight suggestions were received for stimulating business, some of which will be mentioned in this report.

The replies as to the number of old houses wired in the various cities range from 10 per cent in Brooklyn, N.Y., to 98 per cent. in Seattle, Wash., showing a larger percentage of unwired houses in the East than in the West. The rate of current varies from two and eight-tenths cents per kw. in Portland, Ore., to 16c per kw. in Southampton, N. Y.

The data received regarding the prices for which this work is being installed, will be presented in another part of this report.

All of these replies will serve to show that, first, the central stations throughout the country are co-operating with the contractor-dealers, for extending their services into old houses now unwired, and that conditions are steadily improving in this respect from day to day. Second, that in the East and also in the thickly settled cities of the West, a large opportunity awaits the electrical contractor-dealer for securing old house wiring business. Third, that the rate for current is cheapest where the larger number of users of electricity reside, and by increasing the installation of wiring in more homes the cost of current should be reduced. Fourth, that not sufficient activity has been shown by the contractor-dealer either to actively solicit or adopt newspaper advertising. They have been content to remain dormant and allow the central stations to build up large organizations to solicit and secure house wiring business, instead of stimulating this business individually or co-operating with the central station to do this work, for them.

Your Committee has also communicated with a number of cities in which the central station and the contractor-dealer are already co-operating on a satisfactory basis. These cities are now carrying on active house wiring campaigns, the result of which show wonderful progress towards a closer understanding between these two important branches of the industry.

From the figures available, it is estimated that over 24,000 homes were wired during the six weeks of this drive. In a number of these cities, the contractor-dealer and central station are continuing the campaign with further success.

Contractor Dealers Working at a Loss

Returning to the prices, which are now being charged by the contractor-dealers for the installation of old house wiring, the replies to the questionnaire develop the fact that the majority of the contractor-dealers are doing this work at a loss, when they should be receiving a reasonable profit,

over and above the cost of labor and material, plus their actual overhead. The prices range from \$2.00 per outlet in Battle Creek, Mich., as well as two cities in Illinois, to \$5.25 per outlet in Louisville, Ky., and \$5.00 per outlet in Baltimore, Md. These prices show definitely that the work is not being figured on an intelligent basis and that a majority of our members should first be educated and informed as to the proper cost for installing house wiring; amount of material required; the proper manner of installing the work profitably, and the cost of labor for placing the work.

It is not necessary to do this work at a loss to secure the business, as has been the habit in the past of a large number of contractors, as well as some of the central station companies, as the majority of house owners are supplied with increased funds at this time, and statistics show that they are spending more money for luxuries than ever before, and electricity is not a luxury.

We are also assured that prices for labor and material will not materially decrease, and that every indication points to a long period of prosperity. It is therefore important that the electrical contractor-dealer take stock of himself and the prevailing conditions, forget what has been charged for this work in the past and settle down to a basis, where he knows his actual present cost and necessary overhead and charge a reasonable profit for his services.

That contractor-dealers in every city where there are local associations, appoint a committee to meet with a representative of the local central station, to discuss the proper methods of securing the house wiring business in their community. The committee should know the actual cost of labor and material entering into the installation of old house wiring, and to secure this information, every member should submit his cost sheets, showing the past cost to the contractor-dealer. This committee can then tabulate and disseminate the information. The central station could then distribute all the work to the contractor-dealer, pay them when the work is completed, collecting from the customer either on regular terms or on deferred payment, as may be most desirable.

At this time it might be well to suggest that the deferred payment plan has been very popular and has resulted in securing increased house wiring orders; therefore, an arrangement that would permit the contractor-dealer to secure the business and turn it over to the local central station to make the monthly collections, would be preferable. The Morris Plan Bank, who already have branches in a number of cities throughout the United States, are prepared to handle the deferred payment business, if the contractor-dealers prefer to work individually.

A number of contractors have stated that they do no house wiring, because it is not profitable, and the reason it is not profitable is simply that no attempt has been made to keep accurate cost sheets. This is most important; know your cost and then go after the business with a reasonable profit.

Many contractors have no systematic method of estimating house wiring, either a back of an envelope or a business card is considered sufficient for estimating any size job. Your Committee would recommend for unit price estimating, a form similar to copy attached, which gives sufficient space to properly note each room, outlet, switch, plug, etc., and allows less opportunity for omitting necessary parts of the estimate, which usually results in a loss to the contractor-dealer.

Your Committee has learned that a number of contractors in the past have found it necessary in connection with house wiring installation below \$300 to add 50 per cent to the net cost of labor and material in order to be properly covered. This for the reason that the overhead on this class of work is higher than store, industrial lighting or power

installations. The average time required to wire a three-storey house is from five to fifteen days; the cost of material is about 40 per cent of the total cost of the work, labor representing the balance, so that the time necessary to install this class of work is of such duration, that it is necessary to add a larger percentage to cover the increased overhead.

In all house wiring, use only the best materials, recommend to the owners that switches add to the convenience of the installation and should be placed for all important rooms. Do not place the control of electricity in the same class as the old-fashioned gas jet—and now the appliance outlet; study the requirements of each room and suggest to the customers the advantage of having a number of these outlets placed throughout the house; the average customer having electricity installed for the first time, is not familiar with these conveniences, and the contractor-dealer is the one to urge the installation of the same.

Your Committee would further recommend that the contractor-dealer advertise more freely, intensive campaigns, during the spring and fall to be followed up by active solicitation at all times, would result in increased business. Every contractor-dealer should co-operate with his local association, the Society for Electrical Development, and any group of contractor-dealers that might be established, to develop house wiring business.

Selection of Wiremen Important

So many home owners associate the installation of electrical lighting with endless dirt and mess and the tearing out of walls and plaster, it is therefore extremely important to educate the public that wiring can be installed without the discomfort, trouble and inconvenience; only trained and careful wiremen should be employed on house wiring. They should be instructed to begin work on the top floor, finish up the work in each room before going into another and completely finish each floor before starting the next. This may seem like a trivial explanation, but it is with the idea in mind of reducing the labor cost through the proper education of the wiremen to methodically install this work, which will result in more houses being wired at reduced cost to the public; therefore a proper selection of wiremen is recommended; those who are neat, careful and courteous will appeal to the house-wife.

It would be wise to give these men the opportunity, at regular periods, of discussing with each other what they have found to be handy kinks in saving time in the installation of house wiring; this in itself would make the labor factor less uncertain and at the same time reduce the cost of the work.

Your Committee further recommend that central station and contractor-dealer as well, should discourage the installation of lighting outlets for single drop cords without switches or convenience outlets; simply to place electric current in the home.

Experience has proven that the public is usually dissatisfied with this class of work, while the recommendation of a satisfied customer means increased business, quality work should be the keynote of every contractor dealer's policy, and no consideration should allow it to be sacrificed.

I would strongly urge that contractor-dealers tie in with the national advertising that the various manufacturers are publishing in the weekly and monthly magazines, as through this unification we should reap the benefit of the millions of dollars that are yearly being spent to advertise electricity. This can be accomplished by timely window displays, attractive stationery, intelligent salesmanship and systematic follow-up calls and letters.

I would therefore suggest before closing, that some uniform method be established for estimating new and old house wiring, and when perfected, be submitted to the membership.

How I Increased My Sales 100 Per Cent.

I am a salesman for a well-known Canadian firm handling farm lighting and power plants. Like everything else these days it's a case of selling "service." The farmer doesn't care much about our equipment—he has lots of machinery to look after already—but he has been around in his motor car and seen how towns and cities are nicely lighted up at night and so he is beginning to realize that when he gets back home it's pretty dark around the house and barn. This applies to the young people especially who are not so set in their ways.

It's a slow enough job though getting after the farmers one by one and so I take advantage of every opportunity of impressing them collectively. For regular demonstration work I have a 1 kw. plant mounted on a light motor truck and during the past couple of months I have been making a specialty of rural evening gatherings, especially garden parties. It is true enough that young people don't always want too much light at such functions but in this case it's such a novelty that they flutter around it like moths and this better system of lighting has become so great an attraction and has improved the attendance so greatly that I and my plant are in constant demand.

I make no charge for the service supplied—about fifty 20-watt lamps—except that the printed notice must state that "the grounds will be illuminated by—light." Of course if the chairman cares to make a few flattering remarks—and he invariably does—I don't raise any objection. This plan yields us big dividends for two reasons: (1) We demonstrate to a large number collectively and (2) we catch our customers at a time when they are in their most receptive mood. They like the idea of carrying this holiday spirit, this brightness, into their homes and their daily work.

In the winter I expect we shall attend the evening entertainments, Christmas trees, home dances and so on. The farmer is a good fellow when you get under the skin—not too anxious to part with his money but liberal enough on occasion. He likes his telephone and his automobile—and he'll soon be liking his power and lighting plant just as well.

The Canadian Hart Accumulator

The Canadian Hart Accumulator Co., Ltd., has been reorganized, the management having been placed in the hands of a Canadian directorate. On account of their living on this side of the Atlantic, it is expected that the new directorate will be able to serve better the interests of the Canadian trade. Their first step in this direction is the opening of a sales office in Montreal at Room 619, No. 511 St. Catherine St. West. The Canadian company was established in St. Johns, P.Q., five years ago, for the Canadian trade, the parent company being the Hart Accumulator Co. Limited, Marshgate Lane, Stratford, London, Eng., contractors to His Majesty the King, H.R.H. the Duke of Connaught, His Majesty's War Office, Admiralty, India Office, General Post Office, etc.

The general principles of construction of the cells manufactured follow that of the English works, but vary in certain details to meet Canadian conditions.

Positive Plates

For the stationary type batteries, the Hart cells are fitted with demi-Plante positive plates, being a combin-

ation of the Plante & Faure types. The grids are cast with a solid diaphragm with approximate 12 horizontal ribs per inch, and the grid is then filled with special active material having high porosity, which permits of free circulation of the electrolyte in the pores. The grid is not chemically formed, but owing to the repeated cycles of charging and discharging, during the course of working, a skin of oxide is gradually formed all over the grid surface. This formation is produced very gradually and is said to be tougher and more homogeneous than the oxide formed on the grid surface by active chemical attack. The gradual formation of peroxide on the plate by this natural process enables the full capacity to be maintained, and although after several years working the active material, which was initially filled in the plate, may have disintegrated, it is always replaced by the naturally formed oxide. The centre diaphragm makes the grid very strong, preventing buckling under normal working conditions.

The construction of the positive plates described above is too heavy for traction or portable purposes. For this class

An accumulator installation

of work, therefore, the positive plate is constructed of an antimonial lead grid having ribs in alternate arrangement thereby securely locking the active material in position. By a special process the active material is rendered very hard and, consequently, extreme durability is obtained, as in course of working it is the positive plates which have to bear the maximum stresses.

Negative Plates

For both stationary and portable work the negative plates are substantially of the following construction: The grids are of an interlaced type in which the active material consists of long pellets of oxide held in position by vertical ribs alternating on each side of the plate, thus securely caging the active material and preventing dislodgment. The special oxide which is used has an expansive property which counteracts the tendency to shrinkage which might otherwise occur, and in this way the full capacity of the plate can be maintained during the whole life. For portable work it is essential that the weight be reduced to a minimum and, consequently the antimonial lead grids are lighter castings in proportion to the larger grids; which are of pure lead for the stationary batteries.

Separators

For the stationary type, the separators are in the nature of wood boards, having ribs cut solid from the board and with two extension legs at the bottom for supporting the separator in position between the plates. For the portable type of cells the separators are of similar construction, but

without the extension legs, as the plates in this class of battery rest direct on bottom blocks, whereas in the former, the plates are hung in suspension and a clear space is left underneath. In the traction type of batteries, thin hard rubber perforated sheets are also fitted in conjunction with the ribbed wood sheets, the former being placed against the positive plates and touching the ribs of the wood sheets, the smooth side of which will consequently be against the negative plates. It is, of course, necessary that the wood sheets be chemically treated to extract all injurious materials which would harm the plates, and in the usual finished state the wood separators are highly porous and entirely free from resins, oils, etc.

Connections

For stationary cells up to approximately 1100 ampere-hour capacity patent non-corrosive terminals are fitted. The connection consists of special lugs burnt to the positive and negative sets of the cells, the lugs having tapered holes in which are fitted a bolt having corresponding taper. The lugs and connecting bolts are entirely of lead and antimonial lead and consequently there is no possibility of corrosion. When required the cells can be solid-burnt, this being the usual practice with the large batteries for central stations, etc.

Cell Boxes

Up to approximately 800 ampere-hour capacity, glass jars can be provided, but for larger sizes, lead-lined tanks should be used. For the portable types the general practice is to have sealed hard rubber jars.

The Harland Engineering Co.

Mr. A. C. Barfield, manager of the Harland Engineering Company, has recently returned from England, where he has been able to arrange for a number of special and exclusive agencies in connection with electrical equipment, which includes: Berry's Fool Proof Iron Clad Switch Gear; Graham's Loud Speaking Waterproof Naval & Mining Telephones; the Magicoal Electric Fire and Heater; the Telautograph; the J. C. Repeater for long distance telegraph lines, and other interesting equipment which are, they believe, likely to appeal to the Canadian market. The Harland Engineering Company have also recently placed on the market a new electrical interlocking individual motor drive for paper-making machines, which is claimed to be a long way in advance of any such equipment at present on the market. Mr. E. B. Archibald has been appointed to handle this particular section. The firm will be glad to answer any enquiries in regard to any of the above equipments at No. 102 St. Antoine St., Montreal.

Metal Studios, Limited

Metal Studios Limited has recently been granted a Dominion Charter, with head office in Hamilton, Ontario. The new company is manufacturing artistic lighting fixtures for the trade. The organizers are S. Nelson, president; A. Somerville, vice-president, and J. Payne, secretary-treasurer. All these members are expert craftsmen, and have a thorough knowledge of the fixture business acquired through twenty years' experience, and are thus in a position to produce artistically designed goods of superior quality and finish. They have a good organization, proper facilities for manufacturing, and goods are made under intelligent, experienced superintendence by men in whom honest workmanship has become a habit. The success already achieved by the Metal Studios line is evidence of the quality they are putting into their product. They state that they are getting repeat orders daily from satisfied customers. The factory address is 21 Walnut Street, W., Hamilton.

The Zeus Arc Welder

Under the stimulus of war's demands, arc welding increased to a large extent. It is claimed that the Zeus a.c. arc welder, marketed in Canada by J. D. Lachapelle & Co., Montreal, is efficient, speedy, low in consumption of current, and certain in operation. It consists of a specially designed transformer, with a regulator for the various sizes of work. The inherent reactance of the machine automatically stabilizes the arc and prevents the burned weld due to excessive arc length. On the assumption of a 1 c. rate per kw.h., the operating cost is 3 to 4 c per hour. The transformer is oil-cooled. The welder is adapted for overhead welding and is built on the unit system.

The British Government proposes to spend 15 million dollars on telephone extension during the current fiscal year. Five millions will be spent on underground cables and the balance on exchanges and local works. It was admitted in the House of Commons that the service is not satisfactory, but it was said that efforts are being made to improve it. Rates are to be raised.

The death occurred in Nanaimo, B.C., recently, of Mr. Wm. Archibald, who, until the time of his retirement, six years ago, was manager of the C.P.R. telegraph office in that city. He had been in the telegraph service since the age of 14 years, and handled the first cable message ever sent across the Atlantic which was addressed to the president of the United States by the late Queen Victoria.

Mr. G. H. Evoy has recently opened an electrical store at 926 Barton Street East, Hamilton. He will carry a stock of fixtures and supplies and will also engage in wiring-contracting.

Mr. Louis R. Grimshaw, secretary-treasurer Canadian Crocker-Wheeler Company, Limited, St. Catharines, Ontario, died on August 6.

E. A. Wark, Hamilton, Ont., has opened new premises at 31 Mary street, for contracting, fixtures and supplies. He was previously at 167 King Street, East, the location now occupied by Messrs. Hunter & Strome.

Current News and Notes

Brantford, Ont.

The Robbins & Myers Company, of Springfield, Ohio, have announced their intention of establishing a Canadian factory at Brantford, Ont. The company anticipate having about 300 employees at the start, and it is understood they will export extensively throughout the British Empire.

Bridgeburg, Ont.

Surveying has commenced in connection with the projected Hydro radial line from Port Colborne to Bridgeburg.

Hamilton, Ont.

Fares on the Hamilton Radial Railway between Hamilton, Burlington and Oakville, have been advanced. The 25 cent return fare to Burlington is now 45 cents and the 65 cent fare to Oakville is now \$1.00. Special commutation tickets are issued for those who use the line regularly and are considerably cheaper. The Burlington citizens, objected so strenuously to a proposal for increased fares when it was brought up some months ago that the matter was temporarily shelved. It seems now, however, that they must accept the inevitable.

Islington, Ont.

The Ontario Hydro Commission have been granted permission, by the Etobicoke township council, to erect a pumping station on Mimico Creek for cooling the new transformer which is to supply power for Mimico, New Toronto, Etobicoke and the township of Toronto. At present the power is distributed from Cooksville.

London, Ont.

The London and Port Stanley Railway has turned over to the city of London the sum of \$48,000 in full payment of all accrued interest and sinking fund charges and, in addition, \$10,000 for rental due. The line is said to be in a very prosperous condition.

Montreal, Que.

The Sunshine Lamp and Supply Company, Montreal, have been granted letters patent. The capital stock is \$20,000 and the head office Montreal.

Mount Lehman, B.C.

The farmers in the district of Matsqui have appealed to the Western Canada Power Company for a supply of electrical current for their farms.

Perth, Ont.

The Perth Hydro-electric Commission have announced a program of improvement for the town's street lighting system.

Port Arthur, Ont.

A newspaper item states that Sir Adam Beck, chairman of the Ontario Hydro-electric System, has offered to take over the railways of Port Arthur and Fort William and place them on a paying basis under one management.

Port Colborne, Ont.

By a majority of 141 the ratepayers of Port Colborne, Ont., recently approved the by-law authorizing the purchase of the distribution system of the Ontario Power Company from the Hydro-electric Power Commission and for the issuing of debentures to the amount of \$40,000 to cover the purchase and necessary extensions.

Quebec, Que.

Lapointe & Cote, Limitee, have been incorporated with a capital stock of \$49,000, and head office Quebec, Que.

Among other things they are empowered to carry on the business of electricians.

Toronto, Ont.

The Excelsior Electric Dairy Machinery, Limited, has been granted letters patent under the Ontario Companies Act. They will take over the present business of the Excelsior Electric Manufacturing Company and the Excelsior Electric Limited, and are empowered to manufacture and deal in electric motors, machinery and equipment of all kinds. The capital stock is \$100,000, and the head office Toronto.

An interim balance statement and revenue account submitted to the city council by the Toronto Hydro-electric System for the half year ending June 30, shows a total income of \$1,193,054.81. The expenditures are as follows: Electric current, \$327,771.71; expenses of operation, management, repairs, etc., \$346,082.09, a total of \$673,853.80, leaving \$519,195.01 as net income from operations for the period. This has been applied as follows: Interest, \$204,295.54; sinking fund, \$79,276.17; balance for depreciation and adjustments, \$235,623.72. The total revenue of \$1,193,054.81 compares with \$1,157,108.44 for the corresponding period in 1918. The balance for depreciation and adjustment last year was \$154,663.36.

The Hydro-electric Power Commission of Ontario have made formal application to the Minister of Finance at Ottawa to reimburse them for expenditures made on behalf of the municipalities on extensions to supply necessary power for the manufacture of munitions and war materials ordered from time to time by the Dominion Power Controller.

Vancouver, B.C.

Members of the B. C. E. R. office staff recently held their fourth annual picnic at Bowen Island. The attendance was about 340 and the officials of the company, including Messrs. George Kidd, W. G. Murrin and F. R. Glover, assisted in the festivities.

West Vancouver, B.C.

The council of West Vancouver, B.C., are negotiating with the B. C. E. R. Company for a supply of light and power. The B. C. E. R. Company will co-operate, it is understood, providing they are given an exclusive franchise.

Personals

Mr. H. D. Stock, for some time manager of the Bell Telephone branch at Belleville, Ont., has resigned to go with the Wood Milling Company of Hamilton.

Mr. Daniel Toomey, for many years district superintendent of the Niagara, St. Catharines & Toronto Railway System, has resigned, and Mr. O. C. Elliott, who has been acting as special agent of the railway has taken his place.

Mr. C. W. Wiggs, (Capt. Canadian Army Pay Corps) Quebec, after almost five years' service overseas in France and England has re-entered commercial life. At the first meeting of the directors of the Mechanics Supply Co. Limited, of that city, since his return, he was elected a director of the company. Owing to the retirement of their sec.-treas., Mr. W. C. Teackle, who recently resigned to take a more lucrative position with the Herman Young Co., this joint office has been filled by the appointment of Mr. W. R. Wilkinson as secretary and Mr. C. W. Wiggs as treasurer.

Electrical Books—Special Prices

The following Books are Offered Subject to Previous Sale:

- "American Electricians' Handbook, a reference book for practical electrical workers, by Terrell Croft. 712 pages, with over 900 illustrations. Published by McGraw-Hill Book Co. Price \$2.00.
- A Handbook on the Steam Engine, by Herman Haeder. Published in 1914 by Crosby, Lockwood & Son. 522 pages, illustrated. Price \$3.00.
- A Laboratory Manual of Alternating Currents, by John H. Morecroft, E.C. Published in 1912 by Renouf Publishing Company. 248 pages, illustrated. Price \$2.00.
- Baudot Printing Telegraph System, by H. W. Pendry. Published in 1913 by Whittaker & Company. 144 pages, illustrated. Price \$1.00.
- "Central Stations," by Terrell Croft, 1st edition published in 1917, by McGraw-Hill Book Co., Inc. 332 pages, illustrated. Price \$2.50.
- Direct-Acting Steam Pumps, by Frank F. Nickel. Published in 1915 by McGraw-Hill Book Company. 258 pages, illustrated. Price \$3.00.
- Direct Current Machinery, Theory and Operation of, by Cyril M. Jansky, B.S., B.A., 1st edition, just published by McGraw-Hill Co., Inc. 285 pages, illustrated. Price \$2.50.
- Dynamo-Electric Machinery, by Francis B. Crocker, E. M., Ph.D. Published in 1908 by American School of Correspondence. 236 pages, illustrated. Price \$1.00.
- Electric Arcs, by Clement D. Child, Ph.D. Published in 1913 by D. Van Nostrand Company. 194 pages, illustrated. Price \$2.00.
- Electric Car Maintenance, by Walter Jackson. Published in 1914 by McGraw-Hill Book Company. 274 pages, illustrated. Price \$2.00.
- Electric Railway, by A. Morris Buck, M. E. Published in 1915 by McGraw-Hill Book Company, Inc. 390 pages, illustrated. Price \$3.00.
- Electric Railway Engineering, by C. Francis Harding, E. E. Second Edition. Published in 1916 by McGraw-Hill Book Company. 416 pages, illustrated. Price \$3.00.
- "Electric Traction," a treatise on the application of electric power to tramways and railways, by A. T. Dover. Published in 1917 by Whittaker & Co. 661 pages with 518 illustrations and five folding plates. Price \$6.00.
- Electrical Injuries, by C. A. Lauffer, M.D., published in 1912 by John Wiley & Sons. 77 pages. Price 50 cents.
- Electro-Dynamics, by Charles Ashley Carus-Wilson. Published in 1898 by Longmans, Green & Company. 298 pages. Price 50c.
- Elements of The Infinitesimal Calculus, by G. H. Chandler, M.A., Prof. Applied Mathematics, McGill University, 318 pages, cloth bound. Published by John Wiley & Sons, 1907. Price \$1.40.
- Elementary Principles of Illumination and Artificial Lighting, by Arthur Blok, A.M.I.E.E. Published in 1914 by Scott, Greenwood & Son. 235 pages, illustrated. Price \$1.00.
- Elementary Graphic Statics, by John T. Wight. Published in 1913 by Whittaker & Company. 226 pages, illustrated. Price 75c.
- Elementary Magnetism and Electricity, by Cyril M. Jansky, B. S. Published in 1914 by McGraw-Hill Book Company. 212 pages, illustrated. Price \$1.50.
- Examples in Alternating-Currents, (Vol. 1), by F. E. Austin, B.S. Published in 1915. 223 pages, illustrated. Price \$2.00.
- Examples in Magnetism for Students of Physics and Engineering, by Prof. F. E. Austin, B. S. Published in 1916. Price \$1.00.
- First Aid in Case of Electrical Shock, by Dr. John Woodman. Published in 1908 by the New York Edison Company. Illustrated. Price 50 cents.
- "Fuel," by C. F. Herington, recently published by D. Van Nostrand Co. 211 pages, with 84 illustrations. Price \$3.00.
- Handbook of Machine Shop Electricity, by C. E. Clewell. Published in 1916 by McGraw-Hill Book Company. 461 pages, illustrated. Price \$3.00.
- How to Make High-Pressure Transformers, by Professor F. E. Austin. Second edition, just published. 48 pages, illustrated, price 65c.
- Induction Coils in Theory and Practice, by Prof. F. E. Austin. Published this year by the author. 64 pages, illustrated. Price \$1.00.
- International Library of Technology, Vol. 11.B, on Electricity and Magnetism, Electrodynamics, Electrical Resistance and Capacity, The Magnetic Circuit, Electromagnetic Induction, Chemistry and Electro-Chemistry, Primary Batteries, Electrical Measurements, 585 pages, fully illustrated, half Morocco bound. Published by The International Textbook Co., 1905. Price \$3.50.

Publisher's Notice

Advertisements under "Situation Wanted" or "Situation Vacant" are charged at two cents a word per insertion, minimum charge 50 cents.
Advertisements for tenders, equipment, wanted or for sale, etc., or miscellaneous, are charged at \$2.80 per inch.
All advertisements must be in the publisher's hands by the 10th or 23rd of the month to insure insertion in the subsequent issue.

Motors For Sale

We have for sale about 100 D. C. motors, ranging in size from 5 H. P., 1600 r.p.m., to 100 H. P., 430 r.p.m.

These are Canadian General Electric, Chapman & Walker Ltd., and Canadian Westinghouse Company, Ltd. motors.

They will be disposed of under a guarantee of good running condition and prices and terms will be made to suit.

All are offered subject to prior sale.
Itemized list furnished upon request. Write,

LIVE, PROGRESSIVE MANUFACTURERS' AGENT can successfully handle one or more real lines for the Toronto District, now representing established, big selling lines, pertaining to Electrical Trade, wholesale and retail. Box 10, Electrical News, Toronto. 17

More Sockets for More Service

Everyone interested is now convinced that mere mention of "More Sockets for More Service" in a general way is not sufficient. Certain definite concerted steps must be taken to provide necessary outlets for the full utilization of our product—electrical energy.

Very shortly campaigns for added outlets will be as popular as the past house wiring campaigns. But why wait? Why not profit by past experience and at least provide outlets in houses now being equipped for electric service.—N. E. L. A. Bulletin.

Canadian Drill and Electric Box Company, Limited

1402-10 Queen St. East

TORONTO

This Box is Finished with the New Galvanizing Process

of which we are the originators. This process gives a superb finish which is much superior to japan, both in appearance and durability. It resists the acid test.

Our New Service Box No. 1005, 30 Amp., 125 volt, double pole size 8 in. long, 5½ in. wide, 2½ in. deep. It has a carrying capacity up to standard and is approved by Hydro-Electric Power Commission.

Drop in and examine these boxes. They will indeed meet with your approval and verify the claims we make for them.

We carry a complete line from 30 amp., 125 volt up to and including 1200 amp., 600 volt, and we always have on hand from 4000 to 5000 type E. boxes ready for delivery.

Form Steel Boxes, Motor Starting Switches (Steel Enclosed), Motor Drip Pans, Motor Covers, Rheostat Boxes and Accessories

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

THE NATIONAL AUTHORITY FOR TWENTY-FOUR YEARS
THE 1919 EDITION

POCKET SIZE
LEATHER COVER

"STANDARD WIRING"

TELLS YOU HOW

GENERATORS—How to install them, care for them and operate them; all their troubles and how to prevent and cure them; all diagrams showing connections for compound, series and shunt wound machines. How to operate them in parallel or in series. How to protect them and wire them in accordance with the underwriters' requirements.

MOTORS—How to install them, how to protect and operate them. The required amperes, volts or horse power when any two factors are known. How to take care of hot boxes, sparking commutators and other troubles. How to change the direction of rotation when desired. How to start and stop any kind of motor in any class of service. All diagrams of motor wiring. How to find the proper size of wire for any motor for direct current or A. C. single, two or three-phase.

OUTSIDE—Line construction, line wires, service wires, poles and their dimensions and Insulators, guard arms, guy wires, etc. How to install Lightning arrest-

weights, and how to erect and protect them and anchors. Tree wiring, splicing, service and insulators. Transformers with diagrams and instructions.

INSIDE WIRING—When and where to wire. How to find the proper size of wire for current, voltage and drop, either by formulae or by the tables of the book. How to wire for two- and three-phase with formulae and tables in a simple manner that anyone can understand, through partitions and walls and where dangerous surroundings exist. When and how to do it. How to take. The proper way to install Outlets, Junction and Switches for a complete interior conduit. Concealed knob and tube electric and combination electric and gas. How to use it. How to install.

LIGHT AND ILLUMINATION—What is meant by proper and efficient illumination, the latest data on Mazda and other lamps of every candle power and wattage. Direct, indirect and semi-indirect illumination. Where each should be used. Illumination required for various classes of service from show window lighting to public halls and from factories to small residences.

TABLES—Fifty-two tables giving every dimension, carrying capacity, resistance, weight and strength of every size of wire and cable of copper, steel and iron.

All the necessary dimensions, capacities, weights, and other data on conduits, fuses, insulators, lamps, sockets, motor efficiencies, current per horse power of motors. Electrical units and their equivalents. Proper size of wire for all classes of power, light and heating installations. The proper symbols to use to indicate on plans just what is wanted from a motor to a small snap switch with all necessary diagrams.

APPARATUS AND SUPPLIES—A classified list of the leading manufacturers of officially approved wires and wiring devices. Engines, generators, motors, appliances, fixtures, and all supplies necessary for any complete installation from a Central Station to a small cottage.

MONTREAL**CANADA****Cora** Diffusing Domes
for Dining Rooms

*A fixture that is needed in every
modern home in your town*

LIGHTING efficiency is the supreme test of glassware. But in the home the beauty of the ware itself, its design and appropriateness, must also be considered.

This "Cora" Dome is designed for the dining room. It concentrates its strongest light on the table, yet illuminates the whole room. The lamps are entirely concealed, all bright rays are diffused.

The handsome matched shade and bowl are of snowy white "Cora" Glass, etched and tinted in any desired color tone. It is a fixture fine enough for the elaborate mansion, moderate enough for the modest home. That means sales are waiting for you.

Shall we send you prices?

ESTABLISHED 1849
BRADSTREET'S

Offices Throughout the Civilized
World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

THE BRADSTREET COMPANY

Offices in Canada: Halifax, N.S.; Hamilton,
Ont.; London, Ont.; Montreal, Que.; Ottawa,
Ont.; Quebec, Que.; St. John, N.B.; Toronto,
Ont.; Vancouver, B.C.; Victoria, B.C.; Win-
nipeg, Man.; Calgary, Alta.; Edmonton, Alta.;
Sydney, N.S.

THOS. IRVING,

Man. Western Canada, Toronto.

UNIVERSAL BUSHINGS FOR FLEXIBLE TUBING

Neat, Secure and Accessible

Nos. 1 & 3

They grip the flexible tubing securely. Can be installed in a moment by simply slipping over the tubing. Fits "knock out" tightly. Permits easy removal of flexible tubing for inspection without dismantling switch box or injuring bushing or tubing.

Nos. 2 & 4

Universal Bushings

combine function of porcelain, bushing and tape, and give the job a finished mechanical appearance. Try them and be convinced.

Approved by the National Board of Fire Underwriters

"Just What I Want"

This is exactly what you, or any one else, will say after having bothered around with loose extension cords.

The Automatic Extension Reel for Electric Lamps

Obviates the necessity of dragging your cord over the floor, thus wearing out insulation and breaking sockets, guards, etc. Takes your light just where you want it, locks at any point, and automatically rewinds your cord when you are through with light. Contains 25 feet of approved reinforced weatherproof cord.

Approved by the Underwriters, and endorsed by fire and electrical bureaus everywhere. Fully protected by two basic patents and more pending. Write for further particulars and prices.

The Cincinnati Specialty Mfg. Co.
Inc.
1907-19 Powers St., West, Cincinnati, Ohio

Uni-Lectric Lighting Plants

Farm Lighting Standardized 110 volts Direct Current.

Capacity—1000 watts.

Construction — Best workmanship, simple, accessible, compact.

Regulation—Excellent.

Types—Self Starting (push button control) or Hand Crank.

Advantages — No batteries needed — save charging loss—uses standard code wiring, lamps, motors, and appliances—transmits power over larger areas.

Ontario District Agencies Still Open

The Masco Company, Ltd.
91-93 Queen Street East, TORONTO, ONT.

ECONOMY renewable FUSES

are the *right* fuses to protect *your* electrical circuits—

- because they afford the right sort of protection; their reputation lends assurance that you can safely depend on them for accuracy of rating and all-round efficiency in operation.
- because they cut annual fuse maintenance costs 80% as compared with the use of one-time fuses, owing to the fact that an inexpensive "Drop Out" Renewal Link restores a blown Economy Fuse to its original efficiency.
- because it's the work of a moment to replace the link and renew the fuse.
- because a good sized stock of "Drop Out" Renewal Links always on hand represents but a small outlay.

Cut Connection Costs with

these modern little time and labor saving devices. They have displaced blow torch and solder, they have eliminated trouble and uncertainty in making connections on any interior job.

WALGER CONNECTORS

are passed by the National Board of Fire Underwriters and the Hydro-Electric Power Commission for No. 12 wire and under. They make safe, perfectly insulated and permanent connections; make them quickly, smoothly and efficiently. Use Walgers on your next job and the profit you make will buy you

Walgers for the next half-dozen.

Write for sample, also descriptive folder.

Walger 2 Way Connector

For making connections, for lengthening extension wires, and for exchanging fixtures. Simple and convenient.

Chandelier

Ask your jobber

Walger Connector Company

Sales Agent: C. JACKSON, 32 Front St. West, TORONTO, ONT.

Walger 3 Way Connector

To tap feed wires in outlet boxes, in Condulets, or on knob and cleat work. For safe, sure connections.

Advertising is Business Insurance

A large manufacturer who, during the war, devoted his entire plant to war-work, kept his advertising running continuously, although he could not fill a single order. When asked why he did it, he said that he was insuring a market for his product when he returned to his regular lines. He has since reverted to his pre-war products and his plant is running to full capacity with more business in sight than he can handle.

Advertising was business insurance for him.

The Cozy-Glow Radiator

Produces a soft, mellow glow, and throws the heat in any direction,—
A trunion allows the radiator to be adjusted.

A heavy cast-iron base insures firmness. The radiator is readily moved from place to place.

The heating unit, which is easily removable, is wound around a porcelain cylinder, and protected by a copper-wire guard.

Owners of Westinghouse Apparatus are invited to make use of our Service Dept. Repair Shops, where repair work will receive prompt and efficient attention. Repair shops are located at;—

**This SOLENOID SWITCH has been adopted
by the Hydro Electric Commission**

**They use it for
STREET LIGHTING**

Now the fact that it is used by the Hydro-Electric Commission is proof that it is all we claim for it. It certainly is not an experiment, by the fact that it is giving efficient service in many towns throughout Ontario, as well as the other provinces.

No springs, swivels or other complicated mechanisms to give trouble. They close magnetically and are opened by gravity assisted by the tension of the laminated copper contact. All arcing is taken up on the carbons.

Increase the efficiency of your system and decrease the cost of installation by using our Type 17 H.E.P. Solenoid Switches, which are suitable for any frequency on multiple circuit or D.C. Series circuit.

Bank of Hamilton Building

It is interesting

WHEN a large Hydro-Electric Plant installs a 5000 H.P. Silent Chain Drive.

WHEN one of the largest Canadian Manufacturing Plants install over 27 Silent Chain Drives totalling over 4000 H.P.

WHEN a large Canadian City installs a 500 H.P. Silent Chain for driving Generators to provide light for the City.

WHEN a large percentage of our orders are repeat orders.

WHEN practically every Pulp and Paper Mill, Steel Mill, Mine, Grain Elevator, and a very large proportion of the Manufacturers in Canada are Users of either "Renold" or "Morse" Silent Driving Chains.

*Well, you can't help sitting up and
taking notice. Can you?*

True Engineering

In your consideration of any G & W device, first think of the purpose for which it was designed and the work which it is to accomplish and then observe point by point how closely the actual design and manufacture of the device has been held to the simplest and most direct accomplishment of its purpose. There are no unbalanced construction, no elaborate factors of safety against a certain weakness at one point and a palpable lack of safety against this same weakness at another point.

Throughout any design you find true engineering. As an engineer, you know that Engineering in one of its simplest definitions is "the art of avoiding too much or too little." It does not require engineering to accomplish a given work at two or three times what it should cost. It is not engineering to put a flimsy construction in as a part of what is intended to be a permanent construction.

G & W Devices are produced by engineers for engineers and it is from an engineering and operating view point that they should be viewed; if they represent the simplest, most direct method of handling a problem they are exactly what you as an engineer are seeking.

Generation, Transmission and Application of Electricity

Amperehour Meters

Each of Uncle Sam's submarines is equipped with Amperehour meters for indicating battery charge and discharge. The Amperehour meter also indicates how much energy is available from the battery. Years of operation in this service has proved the unfailing reliability of these meters under the most exacting requirements as to accuracy and even under the severe vibration of rapid gun fire. Sangamo Amperehour Meters serve with equal accuracy and reliability on Central Station stand-by batteries, and thousands of other important uses, as, storage batteries for electrical vehicles, trucks, railway train lighting equipment, farm lighting plants, wireless telegraph, etc. The Amperehour principle adds materially to the life of the battery because it prevents destructive overcharging. Let us send you full details.

A Money Making Opportunity for the Electrical Dealer

WITH this can and this outfit you are equipped to undertake any and all glass frosting and etching jobs that come into the place.

ETCH-O-LITE solves all frosting problems. It is permanent, clean, economical in use, uniform in results, and produces a fine, smooth surface. It is so easy to use that the best results may be had from even the most inexperienced help.

For frosting incandescent lamps, electrical measuring instruments, lighting glassware, etc., it has no equal.

Put up in 2½, 5 and 10 lb. containers.

REED'S GLASS ETCHING INK outfit permanently etches glass. It is extensively used for etching names, designs, trademarks, etc. on electric-light bulbs, bottles, or any other glass surface, whether flat, round or irregular.

Both Etch-o-lite and Reed's Etching Ink are non-injurious to skin or clothes. These scientific preparations will return many times their cost to the enterprising dealer in electrical supplies. Write us for booklet and full particulars.

"National Protection"

RUST PROOF—ACID PROOF

A SHERARDIZED surface absolutely protects against rust. By the sherardizing process, the zinc is not merely applied as an enamel to the surface, but is *alloyed with the steel* and becomes a part of it. And more than that, the interior surface is given the same superior zinc protective treatment as the exterior.

A clear acid and alkali proof enamel is then baked on the Sherarduct and affords the best protection to the underlying surfaces against the destructive action of gases and acids. This enamel coating is also applied to the interior surface.

Both surfaces of Sherarduct are sherardized and enameled. "National" Protection is Double Protection. Write for Descriptive Bulletin No. 50.

The Meter of Merit

Write to us—the manufacturers—to-day for particulars.

*British Material
Canadian Workmanship*

The C. & H. Meters have long held the premier position for their accuracy, simplicity and scientifically correct construction.

Besides being absolutely the best instruments you can install for reliability, they represent a combination of Canadian and British production. With the war ended many of the obstacles of obtaining raw material from Britain have been removed, and we are now in a position to make old time prompt delivery.

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Accurate—Rugged—Inexpensive

In factory or field, the Type S set will quickly and accurately measure resistance or locate faults. It will withstand, without detriment to its electrical qualities, the knocks which such a set is bound to get. It is of the Dial Decade Type, and therefore simple to operate. Excellent design plus quantity production enables a low price without sacrificing accuracy—ratio coils 1/20 per cent, rheostat coils 1/10 per cent guaranteed.

The removable suspended coil galvanometer deflects a millimeter per microampere. This combination—accuracy of adjustment of coils, sensitivity of indicator, ruggedness, inexpensive-ness—is found only in the Type S set.

PRICE \$75.00

O-B Base—Form 1

O-B Base Stays Young

All the bearings have renewable steel bushings. It takes only a few minutes to renew these bushings which absorb the hardest wear.

Lubrication and inspection are simple jobs.

A handy hook holds the fork down while the pole is removed in the car barn where head room is minus.

One man lifts the base off the stem casting. The roller bearings are then in plain sight where they can easily be packed with grease. The rollers are caged. They stand up where they belong. They can't jam.

It is so easy to take care of the O-B Base that it usually gets what little attention it needs. So extra years are added to its naturally long life.

THE OHIO BRASS COMPANY

Mansfield, Ohio

Dark parts are renewable bushings

C-G-E Watthour Meters

Painstaking attention to getting the details right is behind the successful performance of C. G. E. Watthour Meters.

At Peterboro, Ont., we maintain a corps of meter experts who are continually on the watch for the slightest sign of imperfection. All that years of meter manufacturing can supply to assure Accuracy, Reliability and Durability is incorporated in the C. G. E. Single-phase Watthour Meter, Type I-14.

In addition to meeting these fundamental requirements the I-14 has but small maintenance and testing expense. Another important feature is its accessibility. For full or light load adjustments, inspection of the register, disk magnets, the removal of the meter cover only is necessary.

The sum total is, a meter in which we have explicit confidence in its ability to uphold the name of C. G. E. Electrical Goods.

REDMANOL

REG. U.S.
PAT. OFF.

"Unbreakable"

R-r-r-ring goes your telephone bell. With mutterings at the disturbance, you snatch at your desk set. The receiver is bounced from its hook. It hits the iron radiator slam-bang as it dangles by its cord. The phone itself upsets; the mouth-piece thumps the desk top with a shattering crash. And wonder of wonders! as you pick the phone up, it is perfectly whole, without a crack or chip. It is Redmanol.

Perhaps these properties will help improve your products:

- Resistance to extreme heat
- Exceptionally high dielectric strength
- Great mechanical strength
- Excellent acid resistance
- Unusual accuracy of dimensions
- Singular beauty of finish

Manufacturers are invited to take advantage of the splendid research work our laboratory is now doing in finding new applications in which Redmanol is markedly superior.

Kraft Cord "Braiduct"

Made in Canada under Canadian Patent No. 147,057

This cut is reproduced from an actual photograph, and illustrates the behavior of the material in this rigid test—perfect flexibility. We cut the ends to show plainly the superior construction—note the high grade Canvas Duck Lining and the KRAFT CORD winding. This KRAFT CORD is made to our own specifications and is fire-proofed, which is entirely new.

KRAFT CORD "BRAIDUCT" is in a class by itself—superior to any imported conduit—is absolutely the last word in flexible non-metallic conduit construction.

We are now making our own insulating compounds, consequently every lot will be uniform in flexibility, and every foot is fished at the factory.

KRAFT CORD "BRAIDUCT" is easy to instal—easy to cut—easy to secure, as it is made in our own country, and easy to buy, as our price is right.

KRAFT CORD "BRAIDUCT" is packed in heavy fibre boxes, each box containing four coils (1,000 ft.), insuring product against damage in transit.

KRAFT CORD "BRAIDUCT" is regularly inspected and labelled by the Underwriters' Laboratory under the direction of the National Board of Fire Underwriters and every coil carries their label.

We will be glad to send you a sample.

Playing Safe on His Motor Equipment

The power user who knows R & M Motor reliability from experience usually insists upon this same reliability when purchasing new motor equipment. And he finds that the best way to be sure of getting it is to make his specifications conform to the nameplate reading on the R & M Motors in service in his plant.

That is the reason the dealer finds it easy to get repeat orders for R & M Motors. Every motor sold is a strong argument in his favor when additional motors are required.

The dealer finds, too, that it is comparatively

easy to sell the initial order of R & M Motors. For through a decade of dominant advertising in the leading magazines, R & M Motor quality has been made pretty well known to everyone. As a result of this advertising the R & M Motor is the one motor which is known to everybody—the man who has never bought a motor before as well as the experienced motor user.

Reliability of operation and the prestige of a name which represents quality to the general public, both favor the dealer who supplies R & M Motors.

MAPLE LEAF BOWLS

The superb quality and lighting efficiency of our "Lumo" and "Moonstone" glassware has had a great influence in making the two-piece popular. The Maple Leaf is one of the most popular and rapid selling fixture made today.

"JEFFERSONLITE"

Made of Moonstone Glass throughout—a semi-translucent glass of high diffusion and reflecting properties. The distinct advantages of this lighting unit are readily seen by an inspection. Send for our new catalogue on these two specialties.

No. 18

The Rights of the Public Must Take Precedence Over Those of Labor

The strike of a few operators on Wednesday afternoon, September 3, in Toronto, which tied the street railway service up for over four hours and inconvenienced in varying degrees a half million people, has done more to alienate the sympathy of the general public from labor as a class than anything that has occurred in recent years. Strikes are wilful waste under the most favorable circumstances, but with conditions as they were in Toronto during Exhibition, it is a strange thing if our laws do not admit of prosecution, as a criminal offence, the men responsible for more than a hundred thousand women, children and babies in arms being stranded miles from home.

Laws in general are made to protect the public. Any action on the part of any individual that endangers the public safety, or causes the public annoyance or inconvenience, is subject to control by law. It is for this reason that our neighbor may not keep musical fowls to awaken us at 4 o'clock in the morning. Neither may he institute revolver practice in his back yard, drive his motor car faster than so many miles per hour, rush past a standing street car in his motor, spit on the sidewalk or in the street car, or roam at large when he is suffering from an infectious disease—the idea underlying all law is that the public has rights which are superior to those of the individual.

Yet here we have a mere handful of men deliberately and intentionally causing pain, sickness and weariness to two or three hundred thousand people. If our laws do not cover

such a case they are stupidly inadequate. If our legislators do not see to it that the men who caused this trouble are severely punished, they will be neglecting the plainest public duty. It is futile to talk about labor's right to strike. The rights of the public must take precedence.

Standardization of Plugs Would Make Appliance Sales Easier

If the Outlet Box Section of the Associated Manufacturers of Electrical Supplies can standardize their products as reported in our last issue, why cannot other electrical products be standardized? What justification is there for a dozen different cords in the average home for use with as many different appliances—these cords all having different plugs at one end and frequently at both ends? What chances are here for annoyance and delay. Frequently, even, appliances are delivered without inquiry having been made as to the plug required and, often, again, where changes have to be made, there is an additional charge—all of which tends to irritate the customer. It is just more of our old policy of making it as difficult as possible for the housewife to become sympathetic with electrical goods.

It may be that manufacturers in general fight shy of standardization because they feel that they have built up a good business on their own particular style which will necessarily be sacrificed for the standard type. But aside from sentiment, where is the loss? The demand for electrical devices would be tremendously increased by such standardization and there would be more business for everybody. Quite aside from that, however, it is poor business to overlook an opportunity for such economy as this would introduce. It alienates the sympathy of the public and sooner or later will react on the industry. Rather let us convince the public that we are working along lines that are in their best interests. Their hearty co-operation, coupled with the satisfaction of developing the industry along right lines will yield the best results in the end.

Minimize Danger of Dust Explosions by Static Charges

The Ontario Fire Prevention League held its annual meeting in Toronto on September 4. Among those who addressed the League was Dr. W. W. Brown of the Department of Agriculture, Washington, on "Dust Explosion." Dr. Brown is an authority on this subject, having made an intimate study of the causes of such explosions in mills, elevators, threshing machines, refineries, and similar structures. The interest in dust explosions has been stimulated in Canada by the recent terrible disaster in the Government's grain elevator at Port Colborne, Ontario.

The Bureau of Mines of the United States Government took up the matter of dust explosions in 1913, as a result of a severe disaster in which many lives were lost.

Funds for these investigations were supplied, at that time, by millers who were anxious to determine the exact causes of these explosions and develop the means for their regulation and ultimate elimination. This work of investigation and experiment was later transferred to the Department of Agriculture, Washington. Since the inauguration of this branch many disasters and fatal explosions have resulted from dust causes, but it speaks well for the investigators that no explosions of a serious character have resulted in any of the plants in which remedial or preventive measures have been installed.

Dust explosions, according to Dr. Brown, are comparable to gas explosions, in that there must be a properly proportioned mixture of dust and gas with the proper spark or

source of heat. No dust explosions can result if either the means of ignition are insufficient or the mixture of dust and air is not sufficiently intimate or properly proportioned. Any dust from a combustible material will explode under these conditions with an intensity that will bear comparison with that of any gas explosion. The pressure developed and the rate of propagation of the flame, in the case of dust, may equal, and in any case will not be much less, than with explosive gas mixtures.

Extensive investigations have proven that the pressure developed and the speed of propagation of flame in many dust explosions is nearly equal to the corresponding pressure and velocity developed in gas explosions. So similar are these explosions that it is not beyond the realm of possibility to expect in the near future internal combustion engines operated by dust instead of gasoline.

To indicate the amount of dust necessary to cause explosion the following figures were given: 23/1000 of an ounce of dust per cu. ft. is sufficient to cause explosion. To utilize all the oxygen in the air 111/1000 of an ounce of coal dust is necessary. With starch dust, this figure is 22/100 of an ounce. It has been found that the dust cloud can be ignited at comparatively low temperatures and, indeed, one prolific cause of explosion is static electricity. This applies for example, to threshing machines in the West, where explosions of smut dust, caused by static charges, have produced destructive effects. Measures adopted to counteract these effects comprise suitable grounding devices attached to the machines in which the static charges are generated. As far as mills and elevators are concerned, the means taken to combat dust trouble are to maintain cleanliness in the plant and to localize the possibility of spread of explosion. By the adoption of suitable methods of isolating various parts of the plant, disastrous results may be very greatly minimized. In addition it is obvious that cleanliness is one of the best fire and explosion preventives to be adopted where dust explosions are possible.

Four Mile Grounded Neutral Transmission Line in Successful Operation

A paper on this subject was recently presented before the A. I. E. E. by Mr. W. S. Richards, covering conditions on a system in Toledo, which was originally delta-connected. The transmission line in this case consisted of an extremely high and long span overhead construction, connected directly to an extensive underground system with its various connections to conversion apparatus.

The system in Toledo was built more on the line of developments following existing industrial requirements than a pre-arranged system where future requirements were anticipated.

In this case, an industry, by reason of circumstances, was located some four miles from the generating station. Conditions were such that it was not desirable for the customer to generate his own supply. His requirements started with a demand of from two to four thousand kilowatts, with the ultimate expected demand of eight to ten thousand. As the industry has exceeded their expected increase, the demand on this system will shortly run to sixteen thousand kilowatts, and possibly greater.

Geographical conditions and city ordinances determined that this transmission should be in part purely underground. There was fortunately located on the route selected, several sub-stations which were badly in need of additional energy and such other developments that the company had in mind, that it was decided to install a 23,000-volt 25-cycle system, it being felt that this was the limit of successful high voltage underground operation. Certain features presented themselves at this time which made it desirable to have the

transformers delta connected. This feature was thoroughly discussed and at that time no serious objections presented themselves and it was put into operation the early part of the year of 1915.

Some trouble developed due to weak spots in cable and joints, but these faults were surprisingly low, considering the quantity of cables that were put into service at this time.

The system rapidly settled down to a successful continued operation and no faults developed that did not have a reasonable explanation, such as fault in material and joints, and joints not properly made.

Since correcting this condition the system has operated successfully with reference to the general plan, but a serious condition arose when a short circuit occurred, particularly disastrous to synchronous apparatus connected with the system, which would invariably fail by reason of the voltage drop occasioned by the severity of a short circuit on the delta system. The cables suffered severely, and in fact, in some cases the covers of the manholes blew off, taking on more the nature of an explosion if the short circuit occurred in the manhole.

It was then decided to change this transmission to a Y system with the grounded neutral. The transformers being constructed for delta operation, it was necessary to take the core out of the case, cut the coils apart and parallel them for 23,000 volts Y. A five ohm resistance was inserted, which afterwards was removed, thereby operating the neutral directly to ground. The results of a cable failure now have a decidedly different effect.

In some cases no superficial evidence is present at the point of failure, and when such evidence is present, it is not of such a severe nature as to destroy adjacent cables and in no way presents the disastrous appearance as when trouble would occur with a system operating delta.

It is true that by experience a better understanding of protective apparatus resulted in changes to such apparatus which were beneficial, but it was felt that the successful operation of this system was largely due to the change from delta to Y grounded.

The system has been in successful operation now some two years and is considered by this company as being successful in all points of construction.

Ontario Hydro Commission Report

The Hydro-Electric Power Commission of Ontario has just issued Volume II of their report covering the year 1918, which includes, among other rates and figures, the 1919 power and light rates for the one hundred and seventy odd municipalities at present supplied by the Commission. As we receive frequent requests for these figures, we are printing them in this issue in somewhat more compact form than they appear in the report.

There are comparatively few changes in either light or power rates from 1918. Indeed it may be taken for granted that, except in isolated cases, there will be few reductions. The changes, if any, are likely to be in the other direction. The cost of electric current is now so low in many parts of Ontario that it represents a negligible percentage of the cost—whether of manufacture or operation; whether domestic or commercial power or light. That being the case it is better that we should concentrate our energies on perfecting the service and popularizing the use of electricity, rather than on reducing its cost.

The A. C. Gilbert-Menzies Company, Toronto, state that the Wallace Lamp is now being put up in lots of one dozen in assorted finishes—brass, bronze, nickel and verde enamel.

Boiler Room Economy in Small Plants

By M. B. Watson, M.E.*

(Concluded from September 1 issue)

The loss of heat occasioned by chimney gases is usually very large because there is no outward method of telling the conditions under which the fuel is being burned and the fireman can not be checked up as he could with loss of coal among the ashes. To realize just what conditions are, special apparatus must be used, and chemical analyses of the chimney gases made. This need have no worry for the average intelligent engineer as will be shown later.

The greatest loss of heat from the stack is on account of the high temperatures of the gases leaving the boiler. About 14 pounds of air are required to burn completely one pound of coal. This air leaves the boiler at probably 600 degrees F. higher temperature than it entered the ash pit doors. It takes about one quarter of a heat unit ($\frac{1}{4}$ B.t.u.) to raise the temperature of one pound of air one degree F. Thus 14 lbs. of air raised through 600 degrees will require $14 \times 600 \times \frac{1}{4} = 2100$ B.t.u's. If this quantity of air were raised through 1200 degrees, it would require about 4200 B.t.u's., or if double this quantity were raised through 600 degrees, it would require about 4200 B.t.u's. Thus we see that the heat carried away by chimney gases varies directly with the rise in temperature, and with the amount of air admitted to the fire.

In order to cut down our losses from Chimney gases, we must keep the temperature of the exhaust gases as low as possible, and cut down the air entering the furnace to the lowest point where we still get good combustion.

To accomplish the latter, the first thing to look to is to see that no air enters the boiler setting or furnace, except where it is required for combustion purposes. The boiler shell must be properly seated in the setting, and no air allowed to leak through cracks in the masonry nor between the boiler shell and the masonry. Also all cleanout doors, etc., must be closed as tightly as possible. Many an hour expended for needlessly polishing parts that show, could be used to better advantage in going over the boiler and setting and stopping up air leaks. Of course the remarks already made about even firing apply here, for a hole in the fire is worse than many large air leaks.

Before we dare cut down the amount of air admitted to the ash pit and the combustion chamber we must know whether the fire is already getting sufficient air to complete the combustion or not. As before stated this can only be determined by a chemical analysis of the flue gases. We will therefore have to look into the matter to see what to expect, and to know the meaning of the results of an analysis.

Only Nitrogen Should Escape

The exhaust gases from the chimney should consist mostly of a large volume of nitrogen, which is the part of the air which does not enter into the combustion, a small amount of moisture, and carbonic acid gas, or carbon dioxide, which is the product of the carbon of the coal completely burned and combined with the oxygen of the air. If too much air is admitted to the furnace, there will also be a large quantity of free air in the chimney gases and the proportion of the other gases to the total will be much smaller than without the air. If insufficient air be admitted to the fire the combustion of the carbon will be only partially complete, and the chimney gases will contain a considerable proportion of carbon monoxide, which is the product when the carbon in the fuel is only partially burned with the air. This carbon monoxide is

a combustible gas and if we allow it to escape through the chimney we are wasting heat which we might have used.

From the above it will be seen that if we can determine the amounts of carbonic acid gas and of carbon monoxide in the chimney gases, we will know whether our fire is getting too much or too little air. The result we strive for then is a high proportion of carbonic acid gas, as little as possible carbon monoxide, and as little free air as possible.

Appliances have been so simplified for such chemical analysis as will give the results required, that any engineer can, by following the directions given, analyze and interpret the results of the analysis of his own chimney gas.

The most convenient and one of the best pieces of apparatus for analyzing chimney gases is known as the "Orsat" apparatus. Investment in one of these appliances will more than pay for itself in a very short time in saving of fuel if the engineer becomes skilled in the use of it and will be guided by the results. By the use of such apparatus, engineers can learn more about the proper operation of the fires than if any other way. Of course when engineers are not equipped for this work, samples of gas can be taken and analyzed by a chemist. These samples should be taken as quickly as possible and note made as to whether taken just before or just after firing. If a sample be collected over a considerable period of time, it will, upon analysis, probably be found to contain both carbon monoxide and free air, as it contains some of the gases formed immediately after firing when there is insufficient air, and later when there is an excess of air. Naturally the results of analysis of such samples are useless. Samples must be taken quickly.

Automatic CO₂ Records

Engineers should impress on the owners or managers of their plants the necessity for, and the enormous saving which can be effected by, the use of such instrument, or even an occasional analysis of this kind done by an outside firm. In some of the larger plants automatic carbonic acid gas recorders are in use. These machines, while quite expensive give indications of the presence of too much air, but give no indication of the presence of carbon monoxide. However, once they are properly adjusted they run with practically no attention and give a continuous record of the proportion of carbonic acid gas thus indicating whether the firing has been regular or otherwise.

It is generally found that the proportion, by volume, of carbonic acid gas in the chimney gas can be as high as 12 to 14 per cent before combustion becomes incomplete and carbon monoxide appears if the firing is done lightly and frequently; while a considerable proportion of carbon monoxide may show itself with only 10 per cent of carbonic gas if the firing be heavy or irregular.

In general the carbon monoxide should not be allowed to exceed $\frac{1}{2}$ or 1 per cent. by volume of the exhaust gases. Although the presence of carbon monoxide shows incomplete combustion and a need for more air, it is no guide to the loss of heat from this source, as there may be other combustible gases such as hydrogen or methane present which, although a loss of heating power, are not often measured.

The obvious remedy for large quantities of carbon monoxide or unburnt gases is to admit more air. The control of this air may seem at first sight to make more work for the fireman, but if done conscientiously will pay for itself in the

*Director of Engineering, Central Technical School, Toronto.

smaller quantity of fuel and ashes to be shoveled, not to mention the cost of the fuel.

Holes in the Fire

Holes in the fire is the most common cause of too much air in the flue gas, which is indicated by a low percentage of carbonic acid gas in the analysis, and is thus a great waste of heat. Frequent firing and the placing of the fuel on the thin spots is the obvious method of preventing the formation of holes in the fire. Firemen may, when operating under small loads, object to frequent firing, because the steam pressure rises to the blowing off point. This is, however, under the control of the fireman by means of the flue damper. When operating under light load, it is obvious that less fuel should be burned, therefore less air is required to be drawn through the furnace. As the bed of fuel is usually thinner under light load than under heavy load conditions, it will be seen that much less draft will suffice to draw this small amount of air through the thinner bed of fuel. The draft can be adjusted to the best proportions by adjustment of the flue damper. The damper regulator should be so arranged that the fireman can operate it from the floor in front of the boiler. A draft gauge, of which the simplest form is the water manometer, a U tube holding water in the bottom of the loop, one end of which is connected to the combustion, or the breeching on the fire side of the damper, the other end left open to the air, will be found of the utmost usefulness in the adjustment of the damper, as it will visualize for the fireman the effects of the movement of the damper. It also gives a good indication of the condition of the fuel bed. If the reading is too high there is either too thick a bed of fuel or else a dirty fire, or when too low there is too thin a fuel bed, or holes in the fire.

When using the damper it should always be moved gradually, as the sudden opening or closing, giving sudden changes of draft is most wasteful of fuel. The ash pit doors should not be used to regulate the draft, for the following reason. If there is too much draft and therefore the fuel is burning too fast and the ash pit doors are closed we will still have a strong suction from the chimney but very little air entering. We will then get incomplete combustion and a great deal of the available heat will be lost.

A thick bed of fuel tends to form crusts and high places, thus requiring more raking and slicing and losing a certain amount of coal, also during this operation cold air enters the fire doors and carries a great deal of heat away as well as putting great uneven strains on the boiler shell or tubes. It will also be found that a thin bed of fuel will form less clinker than a thick one. A good average thickness of fire for a hand fired boiler is 5 to 6 inches of coal on the grates. Thick beds of fuel increases the draft and consequently the air leakage through the fire doors, masonry, etc., while thin beds of fuel let more air than necessary through the fire, unless the draft is checked, heating up this air to no good purposes. From the above it is seen that the thickness of the fire should be kept as nearly constant as possible and the combustion regulated according to the steam required by use of the damper in the flue.

A Perfect Boiler

In a perfect boiler the gases of combustion would first come in contact with a part of the boiler where the temperature of the water or steam was the highest, following along, as the gases give up their heat to the water to the point where the water enters the boiler at a low temperature, leaving the boiler to pass out through the stack at the low temperature of the incoming water.

The above arrangement is of course impossible in practice but efforts are made to repass the hot gases over the boiler surfaces a number of times in order that they may

deliver as much as possible of their heat to the water. If the baffles in a boiler are broken down or have holes in them, the hot gases take the shortest way to the chimney, and do not circulate around the surfaces of the boiler as intended; in this way they escape to the atmosphere at a much higher temperature than if they came in contact with more of the water-cooled surfaces. This under the above conditions only a portion of the hot gases are used in generating steam and much fuel is wasted.

Care should therefore be taken to see that all baffles are in perfect condition and the gases are conducted through the proper paths through the boiler.

Where to Look for Dirt

Since "Cleanliness is next to Godliness," we can no doubt find that it is of use to us in boiler operation.

If the ash pit be allowed to fill up it will be found that the amount of air passing up through the grates will be insufficient, causing the draft from the chimney to become stronger and causing large leakage of air where it is not wanted, at the same time giving incomplete combustion and heating up a lot of air needlessly. The grate bars will be found to burn away very quickly, both because of the heat reflected from the ashes at close quarters, and the insufficiency of cool air passing through and around them. This eventually means a shut down of the boiler and the expense of new grate bars. It is thus of the utmost economy and importance to keep the ash pit clean, as well as to keep the fire clean as we noted previously.

The next place to look for dirt is the fire surfaces of the boiler itself where it collects in the form of soot, dust and ashes. This is easily removed by means of blowers or brushes, as long as it has not been allowed to remain too long in place on the boiler surfaces, and will well repay one for the small amount of work required, if done frequently.

It has been stated by various authorities that a coating of soot one sixteenth of an inch thick on the fire surfaces of a boiler increases the fuel requirements under given load by about 59 per cent. Thus it is less work for the fireman to clean his tubes than to handle all this extra coal and ashes.

When coal containing much volatile matter is burned, there is always a considerable quantity of soot deposited on the tubes and fire surfaces of the boiler, and frequent cleaning of these surfaces is the only way to get efficiency from the boiler. When wood or anthracite coal is burned there will be very little soot deposited, but a great deal of dust and ash is always carried by the draft into the combustion spaces and settles in the tubes, etc. It is just as important to remove this dust as to remove the soot.

The inside or water surfaces of the boiler is the next place to examine conditions. All firemen are of course familiar with scale and sediment in boilers; also many are far too familiar with so called "Boiler Compounds." A little thought will dispel many peculiar notions about scale and sediment. Soft sediment in a boiler is usually the result of mud and sand carried in by the feed water, settling to the bottom of the boiler. This is easily gotten rid of by blowing down at intervals, depending on the amount of dirt in the water.

Scale on the other hand is formed by the precipitation, or settling out of solution, of certain mineral salts contained in the water; chief sulphate, or gypsum. These salts, and some others, have the peculiar property of being precipitated when the temperature of the water is raised. Thus when water containing these salts is heated, they are precipitated out of solution and form a hard scale on the surfaces where the heat is most intense, generally uniting with any soft sediment that may be present forming the whole into a hard scale, in the same manner as lime unites with the sand in ordinary lime mortar, which adheres closely to the surfaces

of the boiler just at the points where the greatest water heating effect should take place.

There is no need here to do more than remind engineers of the enormous waste of fuel occasioned by deposits of scale on the water surfaces of the boiler, also the danger consequent upon the scale becoming thick enough to prevent the water keeping the plates or tubes cool enough not to burn or soften and warp.

The object of any so-called "Boiler Compound," or chemical treatment of the boiler feed water, is to change the chemical composition of these salts to a soluble form, so that they will remain in solution in the water instead of being deposited as a scale. These salts in good solution can be drawn off from time to time by blowing down, and entirely gotten rid of when the boiler is emptied.

The writer has met firemen and even high grade operating engineers, who have picked up, probably from advertisements of cheap boiler compounds, some sort of hazy idea that these compounds will take the scale forming out of the water. Now the only place, except the blow off cock, where anything goes out of the boiler is the steam pipe or safety valve. It is obviously not possible for these salts to go off in the form of steam, as may be demonstrated by boiling a kettle full of salt water to dryness when the salts will still remain.

The process in an ordinary boiler may be likened to the old time method of making maple syrup, where, as the kettle of sap was boiled down, more sap was added, continually keeping the kettle full, until finally a thick syrup was left, part of which would crystalize into sugar if the evaporation were continued further. Thus in a boiler, although we may be able to keep most of the salts dissolved, we finally come to the point where there is such a thick salt solution in the boiler that further boiling will make the soluble salts settle out. By repeated blowing down of the water in the boiler we get rid of part of this thick solution replacing it by thinner solution of new water, thus extending the time when the above con-

dition is reached. However, boilers should be completely emptied as often as possible, in non-condensing plants.

The kinds and quantities of chemicals to use for keeping the scale forming salts in solution can only be determined by a chemist, by analyzing the feed water. The chemist can then advise exactly what quantity of each of certain chemicals should be added per thousand gallons, or pounds, of raw feed water. Of course, condensate from exhaust steam does not contain these salts, so the make-up water only should be allowed for in condensing plants. This necessitates a metering device of some kind for the feed water or make-up water as the case may be. The chemicals should preferably be added continuously in proportion with the water, but daily or even semi-weekly additions of the chemicals are better than large quantities at long intervals of time.

There are numerous testing and chemical companies who will make analyses of boiler feed water and advise as to the treatment at a very small charge. Some chemical manufacturers make a specialty of this kind of work, and make up special mixtures of "Boiler Compounds" to suit the individual conditions of the feed water in question. Great care should, however, be exercised in choosing firms of this kind, that they be thoroughly reputable, and that they publish the results of their analyses and the formulae of their compounds. Beware of all firms who keep these results and formulae secret, or of advertisers of secret formulae Boiler Compounds; as there are, or have been, firms who sell some cheap chemicals, disguised with coloring matter, etc., at ridiculously high prices under the name of Secret Compounds.

Firemen keeping clean fires and ash pits, doing careful firing and draft regulating, and where possible analyzing their flue gases and regulating their fires according to the results shown, also keeping their boilers clean inside and out, will find they can make a great saving in the fuel bill, also a great saving in coal and ash handling which will well repay them for the extra work of close attention. Records in the form of log sheets will also be found of the utmost value in the operation of any steam plant.

Electric Furnace Operation in United Kingdom, 1918

By Mr. R. G. Mercer*

The author's main object is to give any information possible which may tend to increase the general efficiency of electric steel furnaces in this country.

There are installed or being installed 141 electric furnaces with a total capacity of 112,000 kv.a. Of these, 24 are or will be used for Swedish substitute, cupro-nickel, allundum, manganese copper, and ferro alloys.

The remaining 117 are electric steel furnaces having a total charging and kv.a. capacity of 384 tons and 98,769 kv.a. respectively, and a total nominal output of 31,170 tons per month, based on 5 days a week 4 weeks per month.

Assuming that all these furnaces are working at full load, the total nominal output at the end of a year would be 405,000 tons. It has to be borne in mind, however, that some furnaces only work on day shift, others are shut down or not yet installed, and all those in commission have delays due to furnace or electrical troubles and shop conditions. These delays were in many cases very frequent and serious and are referred to below.

Electric steel furnaces are used for steel castings and ingots, and the following tables give particulars of each and the total number, capacity, etc., of each type of furnace.

It will be noted that the Heroult furnace (which was first in the field) heads the list so far as number of furnaces and capacity are concerned.

The Electro-Metals furnace which shows the next highest returns came on the market later.

The Greaves-Etchells, which was produced some time after the Electro-Metals, comes third on the list, and the Stobie furnace, which comes fourth on the list, has only comparatively recently been offered to the steel trade.

The Snyder furnace, which is used for making acid steel, has to rely largely on the steel maker's requirements as to whether he wants to make acid or basic steel.

The two furnaces marked "Special" were made by the user.

Table 1.
Electric Steel Furnaces in the United Kingdom

Made	Number of furnaces	Total tons, size	Total kv.a.	Nominal Tons output per month
Electro Metals.....	27	73	20,274	6,740
Greaves-Etchells...	26	64½	18,830	5,680
Heroult.....	45	180½	43,220	13,760
Rennerfelt.....	4	7	1,895	750
Snyder.....	6	9½	3,150	1,200
Special.....	2	2	750	280
Stassano.....	2	2	600	240
Stobie.....	5	45½	10,050	2,600
Total.....	117	384	98,769	31,170

The nominal output in tons per month is based on 5 days

*From a paper read before the I.E.E.

a week, 4 weeks a month, and the rated charging capacity of the furnace.

Table 2.—Castings
Electric Furnaces for Castings (Installed).

Make	Number of furnaces	Tons, Size	Total kv.a.	Tons output per month	
				Nominal	Actual
Electro-Metals . . .	13	25½	8,139	2,900	—
Greaves-Etchells . .	4	7	2,050	700	—
Heroult	7	16	4,150	1,560	—
Rennerfelt	2	5½	1,100	440	—
Snyder	6	9½	3,150	1,200	—
Special	2	2	750	280	—
Stassano	2	2	600	240	—
Stobie	1	5	800	400	—
Total	37	72½	20,739	7,720	5,019

It will be noted, however, especially in the case of 6-ton furnaces, that the actual charge is, in most cases, greater than the rated charge. This is more fully dealt with later.

Table 2A.
Electric Furnaces for Castings (to be Installed)

Make	Number of furnaces	Tons, Size	Total kv.a.	Tons output per month	
				Nominal	Actual
Electro-Metals . . .	1	2	800	280	—
Greaves-Etchells . .	4	17	5,450	1,260	—
Heroult	4	10½	2,700	980	—
Stobie	2	13½	3,250	600	—
Total	11	44	12,200	3,120	say 2,028
Grand total . . .	48	116½	32,939	10,840	7,047

Table 3.—Ingots
Electric Furnaces for Ingots (Installed)

Make	Number of furnaces	Tons, Size	Total kv.a.	Tons output per month	
				Nominal	Actual
Electro-Metals . . .	12	39½	10,335	3,200	—
Greaves-Etchells . .	10	14¾	4,710	1,570	—
Heroult	32	148¾	34,920	10,720	—
Rennerfelt	1	2	600	240	—
Stobie	1	12	3,000	800	—
Total	56	217	53,565	16,530	12,906

Table 3A
To be Installed

Make	Number of furnaces	Tons, Size	Total kv.a.	Tons output per month	
				Nominal	Actual
Electro-Metals . . .	1	5	1,000	360	—
Greaves-Etchells . .	4	22	4,900	1,650	—
Heroult	1	3½	750	280	—
Stobie	1	15	3,000	800	—
Total	7	44½	9,650	3,090	say 2,410

The actual output giving the best month's output of each furnace is purposely taken and is 65 per cent. of the nominal output (see Table 2).

Assuming that the furnaces to be installed have an actual output of 65 per cent. in Table 2, the actual output per month would be 2,028 tons, making a total of 7,047 tons per month, or 91,637 tons in the ladle per annum, for castings, against a total nominal output of 140,920 tons per annum. It will be readily seen from the above figures that the furnaces are mostly working on day shift (see Table 2A).

The actual output would be 716 tons per month on the month's output of each furnace, and is 78 per cent. of the nominal output (see Table 3).

Assuming these had a ratio of 78 per cent. actual to nominal output as above, the actual output would be 2,410 tons per month (see Table 3A).

These furnaces represent those sanctioned by the Ministry

of Munitions of War, and do not include those ordered since November, 1918, after which date sanction was not required.

Table 3B.
Furnaces (not Working) November 1918

Make	Number of furnaces	Tons, Size	Total kv.a.	Tons output per month	
				Nominal	Actual
Greaves - Etchells . .	4	3¾	1,720	500	—
Heroult	1	2½	700	220	—
Rennerfelt	1	½	195	70	—
Total	6	6¾	2,615	790	say 716

The actual out put would be 716 tons per month on the above assumption.

Table 3c
Furnaces for Castings and Ingots

Class of steel	Number of furnaces	Tons, Size	Total kv.a.	Tons output per month	
				Nominal	Actual
Ingots	69	267½	65,830	20,410	16,032
Castings	48	116½	32,939	10,840	7,049
Grand total	117	324	98,769	31,520	23,081

These figures go to show that, on the above assumption, we have in this country furnaces capable of producing a total possible output of over 300,000 tons of electric steel per annum with 98,769 kv.a. behind them.

Taking the average output per month over a period of time we get very different results, as follows:—

	Nominal	Actual	
Castings	7,720	3,557	46 per cent
Ingots	16,530	9,855	50 per cent

Successful Shawinigan Convention

The two days' convention of the Shawinigan Water & Power Co. at Shawinigan Falls was attended by 350 delegates. The convention was an unqualified success. Mr. J. E. Aldred, president; Mr. Howard Murray, vice-president; Mr. Julian C. Smith, vice-president; Mr. W. S. Hart, treasurer; and Mr. F. T. Kaelin, chief engineer, were among those present.

The proceedings of the convention, held in the Technical School, and presided over by Mr. F. T. Kaelin, were brief, the speeches not occupying more than an hour. The talks were of an informal character. Mr. Julian C. Smith spoke on the importance of efficiency in business and labor, the methods of obtaining same in electrical industries, and its resultant effects on the business of companies. Mr. J. Morse dealt with the supervision of electrical plants. Mr. E. V'inet outlined the measures that the company is adopting for the protection of its employees against injuries and loss of life when working with electrical apparatus. It is proposed to give facilities for practical instruction in this work to employees. "Standardization of Materials and Construction" was the subject chosen by Mr. R. J. Beaumont. Certain points concerning the adoption of such a system were discussed by Messrs. E. B. McDonnough, of Quebec, G. M. Anderson, and W. C. Bean. Mr. C. P. Read pointed out the importance of choosing employees wisely.

The entertainment programme included races, dances, and a baseball game. Refreshments were served after the athletic meet, and the distribution of prizes won in the races took place. The awards consisted entirely of electrical devices.

The Jefferson Glass Company resumed work on August 18 after a shutdown of only six weeks. When the company closed for the summer season, it was not the intention to open up again till some time in September. However, we are advised that rush of orders demanded the earlier opening.

Personal

Mr. C. C. Bothwell, manager Canadian Laco-Phillips Co., sailed on August 30 on the Royal George for a business trip to England and Holland.

Mr. E. T. Garner, Ontario representative of the Jefferson Glass Company, Limited, sailed on August 17, per steamer Metagama on a business trip to England and the continent.

Mr. Matthew Graham, of the Montreal office of the Bell Telephone Company, has been appointed manager of the Bell Telephone Company's Kingston office in succession to Mr. J. A. Gorrie, Jr., who has been appointed manager at Ottawa, succeeding Mr. W. J. Cairns, appointed district traffic superintendent.

Mr. Harry M. Giles has been appointed general superintendent of the South Philadelphia works of the Westinghouse Electric & Manufacturing Company. Mr. Giles, who succeeds the late Oscar Otto, killed in an automobile accident last month, has risen from the ranks in the Westinghouse organi-

zation of marine erection, a position to which he was appointed by H. T. Herr, when the Electric Company absorbed the Machine Company.

Mr. F. D. Egan, former works manager of the Pittsburgh Iron & Steel-Foundries Company, has accepted a position in the general engineering department of the Westinghouse Electric & Manufacturing Company at East Pittsburgh, Penn., where he will devote his entire time to the development of electrical apparatus for steel mill applications.

Mr. Arthur H. Morse, of London, Eng., has been appointed managing director of the Marconi Wireless Telegraph Company of Canada. According to a statement by Mr. Godfrey H. Isaacs, the managing director of the Marconi Wireless Telegraph Co., the Canadian company is to be re-organized, the capital of a millions shares of \$5 each being reduced to \$2.50 each, and 500,000 new shares of \$2.50 each created. The parent company will purchase 400,000 of the new shares and liquidate the debt of the Canadian company to the English company.

Electric Railways

Status of the Electric Railway—Zone System of Fares Applicable to this Continent—Unit Fare Discourages Profitable Short Hauls

By Mr. Dugall C. Jackson*

However serious may be the direct financial disturbances arising if the extensive electric tramway systems in the country decline into bankruptcy, those effects are minor compared with the effects on the prosperity of the country that will result from a failure of systematic local transportation in the cities. The continuation of business in cities, whether industrial, mercantile or other, is dependent on systematic local passenger transportation being available, and the activities and comfort of the great majority of individual citizens are likewise dependent on systematic local passenger facilities. Such facilities must be preserved and enlarged in a character which will maintain them, adapted to the characteristics of the cities.

Most street railways have been organized and work under provisions of some agreement between representatives of a city and representatives of the stockholders. The principles embodied in these contracts are usually similar to those in short-time business contracts, but the conditions are different, and both city representatives and company representatives have been at fault in the past in not recognizing this fact. A company directorate which accepts an agreement to make a fixed fare within city limits which are not defined and may be largely expanded, places the company in a situation where the ultimate bankruptcy of the enterprise is likely to result in case the area of the city grows in large measure, and a city council which insists on such a provision promotes the ultimate strangulation of service as the city grows. But the difficulty has been to find a better way. With the advent of state public utility commissions, the execution of some of the provisions may have yielded here and there to judgment. But even then there has often been a failure to correlate the facts so as to bring out the essential meaning of the tendencies in the industry.

The introduction of supervision by public utility commissions was essentially a move which, uniformly and fairly applied, would result in providing good service at cost, when a fair return on the investment is included as part of the cost in addition to the ordinary daily out-of-pocket expenses. At the same time it affords opportunity for a street railway operated with particularly able, foresighted management and giving notably good service to profit through receiving a larger return on its investment than the average for the industry, since a regulating commission may use its judgment on the question of restricting the return. The present slogan for service at cost adds to this the additional feature of guarantee by the taxpayers of a return on the investment, associated with operation under public

authority. This addition has been adopted in certain instances, but it introduces an inflexibility in the rate of return which may in the future prove unfair to one side or the other. Another solution is to add to the powers of the public utility commissions, giving them sufficiently extensive and experienced engineering and accounting staffs so that they can fully audit the companies' affairs and correctly advise the public in respect to the problems of extension and of operation, without actually undertaking the details of the management. This is a solution to which I believe it is important for your commission to give careful thought.

Our present street railway service is an outgrowth of horse car service which, naturally, dealt alone with the short haul, and the electric railway fares were chosen and fixed by habit on the basis of the horse car service. In that service, the investment per passenger-mile haul was less than in the modern electric service. In Massachusetts the general ratio of total investment to revenue passengers carried per year has gradually but unmistakably increased during the entire period since electrification of the street railways, and the density of traffic measured in revenue passengers carried per car-mile was less in 1915 than at the opening of the period. The service itself has been entirely changed by the introduction of the electric car, which made practicable longer hauls, so that a single fare was paid for hauls which previously cost the passenger two or three fares spent on connecting horse railways. The speed of transportation has also been raised and this has again increased the investment per passenger-mile-haul as well as certain factors of the operating expenses.

Since it is necessary to maintain both the short-haul and the long-haul traffic, it may be inquired whether the electric car is adapted to do this double service. The following considerations bear strongly upon this question:

Rail Lines Better Than 'Buses

It must be remembered that approximately one-half of street railway investment is fixed in the permanent way and adjacent pavement. This proportion has slowly increased during the past thirty years. The jitney buses which run at will on the street surfaces are free from this investment. True their owners contribute by taxes and license fees toward the cost of pavements, but so do the street railways in addition to financing the investment of their own permanent way which is used jointly by other traffic. Moreover, the street railways make heavy investments in power plants of the most economical character, which is a conservation policy as well as a policy for economy, and the jitney does not. These considerations make the jitney business more like other commercial enterprises in respect of the rapidity of turn over of capital and also enable it to compete with street car service operated with flat fares. It is important to examine carefully whether these considerations make the jitney bus lines with systematic routes and reliable schedules desirable substitutes or successors to the street rail-

*Professor of Electrical Engineering, Massachusetts Institute of Technology—Extracted from a statement before the Federal Electric Railway Commission at Washington.

ways, or, at least to a part of their business, as has been asserted.

What would be the effect on the street traffic congestion in cities such as Chicago, Baltimore, Philadelphia, Boston, and a large number of others, if the surface street railway service was replaced by bus service of equal reliability? Many of the American cities each have more than 1,000 cars operating on street railways during their rush hours. To replace such a service with buses would require several times as many vehicles, thereby adding to the welter of street traffic in the heart of each city. These vehicles would cause more than a proportionate addition to the traffic confusion because they would travel at will over the street, instead of being confined to certain definite channels like the street cars. Moreover, additional streets would have to be paved with smooth pavement at greater expense to support this bus traffic. This means a large increase of investment in paving, as well as annual cost for paving maintenance. Given equally systematic and reliable service by street cars and by jitney buses, community economy stands with the street car for service in main channels. The jitney may be made serviceable for certain special conditions. It should also be observed that the use of subways to divert some of the surface traffic from the surface in certain parts of the city, as is done in Boston and Philadelphia, and as is talked of in Chicago, Cleveland and elsewhere, would be less readily accomplished and less safe for railless traffic than for rail transportation. All of these considerations point to the fact that it is necessary under our present conditions of city life to maintain the rail traffic at a high degree of completeness.

Unit Fares Discourage Short Hauls

In my opinion, no amount of repressive regulation will be adequate to do away with the competition which jitney buses produce. If the street railway service cannot be made complete and adequate to the needs, some other service, such as jitney service, will come in as a competitor. In fact, it ought to come in and be encouraged unless means

can be provided to make the street railway service adequate to the needs, and the necessities of the present are to find the best ways of making the street railway service adequate, in view of the fact that it is (with all things considered) the more economical service for the community.

After having studied carefully the conditions of local transportation in American cities under the normal conditions of cost prior to the war, I became convinced that a considerable part of the difficulties of the present street railway transportation systems is due to their effort to satisfy the needs of long haul at the expense of the needs of the short haul. These conclusions are set forth in a statistical report on the subject, published in 1917 in a book entitled "Street Railway Fares, Their Relation to Length of Haul and Cost of Service" by Jackson and McGrath. In the first chapter of this book are set forth a summary and general conclusions. I wish to call your attention to seven paragraphs of specific facts regarding street railways which this investigation, in my opinion establishes.

1. Density of traffic is the most fundamental factor in establishing the cost of service per passenger. The higher the density of traffic, the lower the investment charges and operating expenses per passenger. In this connection density of traffic is a term used to mean passengers carried per car-mile run, and passengers carried per mile of track per annum.

2. Long hauls tend to decrease density of traffic, thus decreasing the earnings per car-mile and increasing the cost per passenger.

3. The average length of passenger haul increases with the length of line.

4. The density of traffic becomes large in medium-sized cities, but as the cities spread out and become very large, the density of traffic tends to decrease again because of long hauls into thinly settled suburbs.

5. Increased unit fares have a tendency to decrease traffic, while decreased unit fares tend to increase traffic.

6. For a number of individual roads studied, as well as for the aggregate of all street railways in Massachusetts combined statistically as a single system, it has been found that the average actual investment per revenue passenger carried per annum has been increasing, and the average rate of return has been decreasing. This has been asso-

Courtesy Monthly Sales Service

ciated in the last few years (considering conditions prior to the European war only) with an upward tendency of operating cost per revenue passenger.

7. Fares in British cities are somewhat lower than on American street railways, and are almost invariably based upon the distance the passenger rides. In general they approximate (before the war) about 1 ct. (U. S. money) per mile and the average ride is usually only about 2 miles. Lower rates abroad may be ascribed partially to a greater density of population per mile of track, while wage scales are much lower in British cities than in this country and free transfers between lines are seldom issued.

[In addition to these seven specific facts, Professor Jackson quoted ten conclusions from his book, setting forth, among other things, that, in his belief, the street railways in the United States, both urban and suburban, would sooner or later be forced to adopt a system of rates based more nearly on the length of the haul. A mileage system of rates would probably be less desirable, in his opinion, than to retain the nickel fare by putting a reasonable limit on the length of the ride permitted for that rate. In general, he recommended, something shorter and more uniform than the present irregular and unsystematic 5-cent zones, possibly with lower unit rates than 5 cents.]

Zone Fares Should be Established

The foregoing conclusions all point to the necessity of some zone plan of fares for our large cities. Where it is pointed out in the conclusions that a mileage system of rates is probably not desirable in American cities, it is the intention to urge the fact that transportation, like other branches of business, has a certain proportion of overhead cost which is reasonably independent of the bulk of the business, and that, therefore, the short haul passengers may be expected to pay a larger fare per passenger-mile apportionment than the long haul passengers, and that the zone system should be laid out recognizing that fact. Zones which might have been based on a 3-cent fare under pre-war cost, would, to-day, call for a 5-cent or larger fare.

Most of the street railways of the United States have wished to avert the introduction of zone fares, partially on account of the difficulty of adequately auditing the fares collected. In the European cities where zone fares have been used for several decades, the plan has been usually founded upon a straight mileage charge without consideration of the stand-by charges, and measures for adequate auditing have not been introduced. This is undesirable in American practice since we have a much heavier passenger flow which calls for larger loads on our cars and makes impracticable the collection of fares according to European methods. Moreover, the American public is more inclined to criticize loose methods of fare collection than the foreign public, and the American public has become more accustomed to methods of checking money collections in all lines of business, as is illustrated by the very general use of cash registers in the mercantile lines, than has the European public. Some of our American street railway employees suggest that the introduction of accurate methods of accounting for fares is a reflection upon the honesty of the platform men on the cars, but, in my opinion, this is an inaccurate inference in respect to the attitude of the true man. No true man can fairly object to the use of a cash register in a corner grocery in which he is employed as a clerk, nor in a department store where he is employed, as it puts him upon his mettle to do his work accurately and is to his advantage rather than his disadvantage if he is honest. Similarly accurate methods can be introduced in association with some fare collections on street railway cars. The passengers can rely upon paying only for that which they get in the way of transportation and can likewise rely upon the company receiving a full accounting from the collectors.

With the normal conditions of commodity costs gradu-

ally returning, as we may expect them to return ultimately, the unit fare may go below the nickel, so that a proportion of the passengers carried should pay less than the traditionally established nickel fare, while those passengers who travel larger distances will, and ought to, pay more than the nickel fare.

Zone Fares Reduce Congestion

Voice has been given to much well meant but incorrect criticism of zone fares for American cities. This has generally been based upon an allegation of population in the cities. My study has satisfied me that these premises are erroneous. The family that has gone to the suburbs for the purpose of obtaining better living conditions, as a rule, is able to pay a slight increase of fare without over-throwing its margin of advantages. If such fares are not increased above 5 cents provided the distance to the suburb is greater than a passenger can be carried for 5 cents, then the loss from carrying such passengers for 5 cents must be borne by others. If it is assumed by the state or city, the suburban dwellers will ultimately pay more than the extra fare, because we cannot escape the proposition that the general public pays for all such costs which are assumed by government, and that the cheapest way of meeting the costs is by direct payment, rather than the indirect payment through taxation.

Moreover, there are a large proportion of unskilled working people living in cities on whom the payment of even 5-cent fares falls heavily, and these, with their families, are now constrained to live in definite portions of our cities often denominated "slums," which are near the locations of centres of employment, because the individuals are unable to pay transportation charges and must live near their work. The zone plan, properly introduced at the present time, may not aid this portion of the population now, but with the gradual decrease of the cost of commodities and the consequent reduction of the price of transportation there will be an ultimate reduction of the unit price per zone, which will enable such passengers to get a certain amount of transportation at less than 5 cents per passenger. The ultimate result of the zone system introduced properly into American cities will improve the present situation by tending to spread the area within which it is practicable for unskilled working people to live.

Canadian Electric Railways Cannot Be Run "On the Cheap"

The U. S. Government recently appointed an Electric Railways Commission to gather evidence on actual conditions surrounding the operation of electric railways, with a view to dealing with the situation. Evidently the government has the idea of instituting such action as will best serve the public interest. They are taking care to hear all sides of the case—railway officials, the public and labor. It is the apparent idea that a poor railway service is dear at any price.

Unfortunately for the public good there are municipalities in Canada whose officials have no such broad gauge ideas. Things must be done on the cheap regardless of quality. The idea is that this plan pleases the public, and pleasing the public means votes. We do not believe, however, that this is the right policy. It is only fair that we pay for what we buy, and we all know that a street car ride costs the operating companies practically double to-day what it did five years ago. Why exact the last pound of flesh just because of franchise agreements that never anticipated war conditions? Why not play the game like a real sport—on the square?

The Contractor-Dealer

Solving the Servant Problem—It's Up To The Electrical Contractor-Dealer

There was a time when housewives needed to be convinced that an electric iron was superior to the old "sad"; that day passed long ago. Since that day, electrical devices, one by one, have been brought to such a state of perfection that they are now recognized without question as standard articles in household furnishings—toasters, vacuum cleaners, ranges, percolators, etc., etc.

And the procession still goes on. Up to the present the electric washing machine has been looked upon with hope rather than favor. It has taken this appliance longer to prove its real labor-saving qualities. Not that there has been any difficulty in selling washing machines—quite the reverse. Once you convince a housewife that it will do what is claimed for it the machine sells itself. But it now seems as if the pioneer work had been done and that this article,

like those that have gone before, is now established as an essential—a real mother's help.

And now, next in line comes the ironing machine and the dish-washer. The field for both is unlimited. Both will get the kindest possible reception and be given every chance to prove their worth. All that has to be shown is that they save labor—that is, save more than they create—and that they are dependable in operation. The latter should be simple and if the present models don't save labor there is nothing for it but to correct the models. This, at best, will take a year or two.

Almost in the same class as the dishwasher and ironer comes the electric refrigerator. There is no piece of furniture in the home more frequently and constantly used. Three times a day, to and from the refrigerator—sometimes located in an almost inaccessible corner—always an expensive appliance to operate with the present-day high-priced ice—generally a nuisance to fill and messy at that—think, by comparison, of the luxury of an electrically operated refrigerator in the kitchen wall—ready to hand, automatically operated—a delight as well as a labor-saver to the kitchen worker.

Servants are scarce and getting scarcer; often inefficient and getting more so; generally independent and unreasonable in their demands and certainly not improving in this direction. The electrical trade holds the solution. There never was a richer harvest or a more urgent need for gathering in.

You Never Can Tell 'Till You Try

Many women are wondering if the Electric Washer really does—

- Save time.
- Save the clothes.
- Wash the clothes clean.
- Wash very dirty clothes.
- Wash the more delicate fabrics.

We tell you that the Electric Washer does all this and more—and scores of women can tell you that we tell the truth.

But find out for yourself. Let us install an Electric Washer in your home. You can use it, test it fairly and if it does not live up to our claims your money will be returned without the slightest trouble.

We'll put a (——) Electric Washer in your home, for \$0.00 down and \$0.00 a month—all on a money-back guarantee.

Call, phone or write today and arrange for the trial.

(Your Name and Address)

To be a successful contractor, or dealer, or both, you must be a good merchandiser, and to be a good merchandiser you must be a good advertiser. Here is an advertising suggestion that will arouse interest in the electric washing idea

How to Meet Competition From Non-Electrical Dealers

Every now and then a note of alarm and protest is heard from contractor-dealers regarding the inroads being made into what they term their legitimate business by the department stores, the hardware and the drug stores. Some talk of taking concentrated action against this development of the electrical merchandising business. Let us examine the situation a bit.

In the first place the sale of electrical merchandise cannot be restricted to any one class of dealers. You can sell other than electrical supplies, if you think it wise. The question is, have you reached the highest point possible in electrical merchandising? If you have, more than likely you are so busy looking after your own business, and it is paying you so well, that you have no time or desire to go into other lines. There is a better way to meet the competition.

People have a habit of giving their business to the merchant who tends strictly to his own special line and does not waste time criticizing the other fellow. Therefore, the best way to meet this situation is for the electrical interests to concentrate upon their own wares; to drive home the message of "Do It Electrically" and "But It From an Electric Shop" to the prospects and customers of their community. The degree to which they do this will determine the amount of business which they will bring directly to the electric shop.

The non-electrical dealers have some advantages. They

will sell electrical goods as more or less of a side line; to you these goods are your only foundation for profit. They will have prospects coming into their store to "shop." Their windows will, no doubt, appeal to a greater number of people than your own. It would appear that they have the opportunity to display electrical merchandise to a greater number of people than you have. But opposed to these advantages you have others, equally as good, if properly used. People are inclined to buy electrical merchandise from the electrical shop. They will buy from you if you make it worth their while.

Intelligent Service

In the first place you should have the advantage of offering really intelligent sales service. In visiting an electrical shop people have the right to expect attention from salespeople who knew thoroughly the appliances which they are selling, who know the right appliance to suggest and who know what a given device will actually do under the right circumstances. The electrical salesman does not have to be technical and use language which the customer will not understand, but he must be able to explain a device to the customer in plain language.

Practically everyone likes to be waited on by a salesman who shows an intelligent understanding of what he is selling. This sort of sales service so far as electrical devices are concerned, is seldom found in the non-electrical competitors store.

Special Attention

You may have to make added effort to get customers into your store. To make it easy for women to buy from

you, you must make your store interior and exterior attractive. Women expect certain things in department stores such as telephone booths, chairs, mirrors and something of a comfortable atmosphere. These things cost little and can just as well give your store the air of being easy to shop in.

Once having secured a customer, even if she bought only a 25 watt lamp, never lose sight of her. She knows where your store is; it will be easier for you now to get her back to purchase more. Follow up your advantage. Your non-electrical competitors have not the opportunities which you have in this matter of personal solicitation. You have the entry into the home—especially new homes—you contractors. You are frequently invited in whereas the other fellow has to invite the prospect into his store. Furthermore, few non-electrical merchants employ outside selling methods. Herein you have a wonderful field before you. Because electrical specialties, for the most part, must be sold—they must be gotten into the prospect's home, demonstrated, and once that is done the sale is almost certain.

Buy at an Electrical Store

Therefore, instead of worrying about the "other fellow" concentrate on your own customers. Organize your outside sales force, brighten up your store and your windows; in your advertising, on your stationery—everywhere you can think of—feature the slogan—"Buy Your Goods at an Electric Store." Get your fellow electrical merchants to do this and co-operate—for your own mutual benefit. The non-electrical dealers do not co-operate. You will have little resistance from that source.

"Service" Defined for the Electrical Contractor-Dealer

By Mr. T. N. White*

The term "service" has an extremely broad application. Its definition, as applied to any one field, is easily understood. You will, however, find difficulty in defining the word service. Broadly speaking, I would define it as "the delivery of something of value to both the giver and the receiver."

Usually service in its commercial application is considered as modern. This belief is erroneous. Service has developed with trade and commerce. Wide-awake dealers and traders have always given service whenever it was of value to both their customers and themselves. The very fact that the word "service" has some eighteen definitions indicates its age. No modern word would have such a broad application.

Let us consider service as applied to Rural Power and Light. You may regard the "service" required by your contract as a necessary evil. As a dealer you claim that it is your business.

First: To interest a prospect in your plant.

Second: To sell the plant.

Third: To deliver the plant and collect your pay.

Fourth: To forget about this customer and devote your time to securing other sales.

This Schedule Leaves Out Service

This schedule leaves out "service," and may be your idea of doing business. Is this the case in your instance? Let us assume that this is your attitude and that you consider service is only of value to your customer. Is your idea correct?

We claim that you are mistaken. Let us assume that you have 10,000 homes in your district. At least half of these are held by people who don't want a plant, or will never have

cash to pay for one. The remaining 5,000 may be considered as prospects. There are other dealers selling plants in your district, so you can't expect to get all the business. Neither can you expect to interest all the prospects in one year.

Let us say that 5 per cent of the prospects can be sold in the coming twelve months. This means that 250 plants will be purchased in your district during the year.

There are other dealers, say two, who are energetic and right after the business. Maybe there are other less enterprising dealers who will get a little business. You should get your share, or about 25 per cent. This leaves the remaining 75 per cent. to be divided among your competitors. You get orders for about 60 plants. You may be satisfied with this or you may not. Your share of the business depends on your efforts. We have given you a very complete line of plants and you should be able to get a large percentage of the business in your district.

This covers one year. You still have about nineteen years' work before you, as you must get your share of business from the 4,750 remaining prospects.

In addition to this new business, your old customers are going to want new plants in ten years or less. Some will require larger plants as they increase their load. The old customers are going to require lamps, flat irons, motors, repair parts for their plants and many other things.

Think this over. Just what is going to happen if you don't give these old customers service. Not more than one third of the customers will stand the absence of service. They expect service to be supplied with this class of apparatus. Several Western Provinces have passed laws requiring service. Evidently manufacturers and dealers were

*At Convention of Western Ontario dealers recently held in London, Ont., by the Northern Electric Company.

not giving service so the customers had these laws passed. We can expect similar legislation here in the near future. Don't put yourself in a false position; your customers will make you correct your attitude or drive you out of the power and light business.

We have estimated that one-third of your customers are going to keep quiet and not cause trouble, but how about the other two-thirds. They are going around among their friends telling them about their troubles. The plant may be all right, but they don't know how to run it. They may need a repair part and you won't get it. There may be any number of little things that you could correct or explain and satisfy them, but you don't. These customers go around and give your plant and your business advertising of the worst kind. They won't buy from you again and they spoil your chances with prospects. They not only ruin your business but they give the entire power and light business a poor reputation.

We have considered what happens when no service is given. Now let us consider real service; how to give service and how to make service pay.

This Schedule Includes Service

Real service means simply keeping your customers satisfied. To be a satisfied power and light user your customer must

- First: Have the plant installed on proper foundations in a suitable location.
- Second: He must have his plant started properly and delivered to him in good running order.
- Third: He must know how to operate his plant and keep it in good order.
- Fourth: He must be able to secure repair parts quickly and at a reasonable price.
- Fifth: He must have confidence that he can get help from you if anything goes wrong.
- Sixth: He must feel that you take a personal interest in his plant and that your interest does not cease when you have made the sale.

How to Give Service

Start giving service just as soon as you get the order. Tell the customer that he must put his plant on a good foundation. All our plants run at a fairly high speed, and it is necessary that a good foundation be provided. We will furnish your customer with a foundation plan on receipt of the order. Poor foundations will shorten the life of a plant from 10 per cent. to 30 per cent. and increase repair bills 100 per cent. to 200 per cent. Get the foundation made at once. Your customer will want to run the plant just as soon as he gets it. If no foundations are ready the plant will be set up "temporarily," and it will, usually, never be changed. Poor foundations mean a constant call on you for service. Protect yourself by insisting on having good foundations.

Next instruct your customer about receiving the shipment. Warn him to examine the shipment carefully before signing for the goods. Knock a few boards off the crates and look the engine over. Examine each battery crate for indications of broken jars. Does battery crate show any signs of acid? Open all battery crates showing acid and inspect the batteries for breakage. This examination should, if possible, be witnessed by the local freight agent. If goods are damaged sign for goods in damaged condition. Usually the agent will allow this examination before you sign. Sometimes they will make you sign first. If this is the case sign "subject to inspection," then make your examination. Call the agent at once in case of breakage. He is obliged to take note of your report in case of damage.

Help your customer with his claim. Our sales manual will soon contain a section covering claims against transportation companies.

ELECTRICITY FOR THE FARM

Northern Electric POWER & LIGHT

POWER for Washing—Churning—Milking—
Separator—Grindstone

ELECTRICITY for Flat-iron—Toaster—Vacuum
Cleaner—Fan

LIGHT for House—Barns—Dairy—Silo—Driveways

WATER for House—Dairy or Barns

This dependable Electric Plant is right now doing chores and household tasks on hundreds of Canadian farms. And also supplying them with bright and safe electric light and pumping the water for house and barns.

It is fully automatic—starts itself and stops itself—one of the five sizes will just fit your farm—There is a sample set up here, come in and see it run.

WALTER H. BYERS, West New Annan

From the Truro, N.S., "News"—A sign of the times

Tell your customer to notify you just as soon as the plant is received and installed on its foundation. Then go to your customer's plant, check over the connections, and see that everything is in first-class condition before you leave. Before going question your customer to see that he has studied the instructions. Make sure that he realizes the importance of the instructions.

Carry a stock of small repair parts so that you can get your customer's plant started in case of breakage. Our warehouses will carry a large repair stock, but don't depend on this stock for your district. You cannot give real service unless you carry small small repair parts.

Don't delay in responding to calls for help. Get right on the job just as soon as you can. A quick response will help you to establish confidence and will please your customers. A customer with a balky plant will soon develop a grouch and it may take weeks or months to overcome his unfriendly feeling.

Look in on Old Customers

When you are covering your district stop and see your old customers. Ask how their plants are running. Inspect the plant, check the gravity of the battery and run the engine. Check the operation of any automatic fixture and see that they are working correctly. If you find anything wrong suggest its correction or, if possible, make the correction yourself. Make your customer feel that your call is prompted by your personal interest in his plant.

How to Make Service Pay

You will, I believe, agree that service is of considerable value to your customer. Let us consider its value to you. There are two sources of income from service. The first, and least important, is the cash received for your time and material. We insist that you make no charge for your first

visit, that is at the time the plant is started. After this call your customer should understand that he must pay for your time and expense. Have this understood before you leave. Our new order blank will state the service conditions. There is one class of service that we may ask you to bill to us. Instruction books are supplied with each plant. If your customer finds trouble not covered by the instruction book, let us know at once, giving us all details. It is part of our service policy to see that all plants are supplied with full and complete instructions. We also wish to see that these instructions are so worded that the customer understands them.

The second, and most important, consideration is good-will. By giving good service you secure the customer's good-will. This is of more value to you personally than to us. It is something that no one can take away from you. If you change or increase the scope of your business this good-will will still be yours and will help you as long as you continue doing business in your district.

Before closing I wish to mention again the importance of calling on your customers and inspecting their plants. You can inspect a plant in ten minutes; a little more time will be required if you make adjustments and talk with your customer. Don't consider these calls as wasted time. By calling, you know the condition of all the plants in your district. You know where you can take a prospect to show him a plant. A well installed plant with a satisfied owner is your best bet. Get your old customer to talk with your prospect. A satisfied customer is your best salesman.

If you don't know the condition of the plants in your district you are liable to take a prospect to a dissatisfied customer. Use the best plants to exhibit. Never show a poorly installed plant to a prospect.

Try to have every plant installed so that it may be used as an exhibit. If one of your customers won't fix his plant, take him to a model installation. Make him ashamed of his own. One or two object lessons will usually result in an improvement.

Fundamentals of Electrical Merchandising

By Mr. W. L. Goodwin*

S. A. Chase and I have just completed a trip which started in New York and covered the entire country, including Canada. During that whole trip we failed to hear a single note of criticism against the business methods of the contractor-dealers. We found a material improvement in their credit standing, as well as in their moral standing.

Today the contractors have the interested attention of every other group in the industry, and you have proved your ability to carry through the tasks that you have set for the industry.

But, speaking in general terms makes it difficult for the average man to apply them to his daily business.

Better merchandising, or merchandising opportunities, are present on every hand, but for you to take them back to your home, and apply them, is the difficult thing.

The trade press of this country have done commendable work in carrying the message of better merchandising. But without your application of the ideas suggested, time has been wasted, and money uselessly spent.

In this travel around the country I ascertained that there is a keen desire on the part of those contractors into that branch of the business. Lack of men to man the institution, and lack of knowledge as to the correct thing to do, has caused many to hesitate upon embarking in the merchandising enterprise.

Notwithstanding that fact, however, some 350 stores have been opened within the past two years, with only one failure recorded, to my knowledge, and that is evidence, in my opinion, that we electrical men have acquired some ability in the conduct of retail stores. Merchandising, in itself, is a very simple thing to those who understand it. It has been said that people must possess a natural ability to conduct a retail business. That is true only to a certain extent. But with men of intelligence and experience, such as most of the men in the electrical industry are, I feel that we have the talent in the organization to carry, for all time in the future, a satisfactory and complete public service on the part of the electrical people.

The Electrical Business for Electrical People

We find in this field of merchandising, the greatest opportunity for development. The way that the electrical men

*Before Convention of the National Electrical Contractors and Dealers' Association at Waukesha Beach, Wis.

are taking hold of this problem convinces me that once more we have set a pace in merchandising that must be followed by other merchants, and that we are once more regaining to the electrical industry that part of the business which was fast getting away from the electrical people. We have, of course, no desire to drive from the business those concerns that take on our lines, as an incidental part of their business. But we do wish to establish practices in the trade that might well be followed by others.

If we accomplish the tasks set before us, in establishing proper policies, and rendering the right kind of public service, then we may be sure that this electrical industry, from the retail standpoint, will be preserved to electrical people. With that idea in mind we are going to present some of the Fundamentals of Merchandising.

The Crying Need

The most crying need, at the present time, is the maintenance of proper retail stores. That is perfectly obvious. And, next to that in importance, to my mind, is the need of improved packing methods—the improvement of packing to the extent that the commodities may be standardized and the cost of conducting the sale of them reduced to a minimum.

The products in the store of the average electrical dealer present a most miserable appearance, and it is utterly impossible for any electrical dealer to maintain a well-ordered store with the products now given to him, the facilities at his command for window displays being totally inadequate for the job to be done.

Proper Boxing Helps Sell Goods

Following that suggestion, several manufacturers have already started to study this question, and improve their packing methods. A few tests that we have made during the past six months may prove of interest to you.

A particular bell-ringing transformer, on display in a retail store in New York City, resulted, as the dealer reported, in the sale of only two transformers in a period of thirty days.

That same product, packed in proper packages, for a proper window display, sold 202 of these bell-ringing transformers in thirty days, proving conclusively that in the first instance the dealer had not been provided with proper facilities to sell the product.

If you contractor-dealers will point out to the manu-

facturers this opportunity to improve the method in getting their products to you, you will decrease your overhead expense.

The most important feature in entering a retail business is location, as we will take occasion to point out later on.

Value of Good Location

The next most important feature is the selection and character of goods known to you, that are saleable in your community. A very good location, backed up by the most efficient management and knowledge of the business, will

Electrical goods should be "turned" six times a year at least. Eight and ten times is not uncommon. The quicker the turnover the fresher the stock, and, in consequence, the quicker the turnover. It's cumulative.

prove unsuccessful, if the merchandise offered is not saleable in the particular community in which the store is located. Local demands represents a large percentage of the opportunity for success.

The enjoyment of large demand does not necessarily mean greater net profits. Increased demand is of no value if the increase in compensation is offset by an even larger increase in selling expense. We should only require reasonable sales effort on the part of the dealer, to make a sale. Therefore, the manufacturers and jobbers must assist you in popularizing the product which they manufacture, in the community in which you operate.

And so you should give much consideration to what I call local demand—a knowledge of a particular product in the local community, and, so far as it is possible to do so, serve that product to your community.

Concentrate Your Business

Next in importance is concentration of business. Much time and money has been wasted by dealers, in an attempt to carry every conceivable product to take care of an occasional demand. Concentrated sales effort on the part of the dealer, on any line or lines that he may select, in my opinion, will produce the best results.

Co-operation of jobbers and central stations in your local community is vital to the success of any retail business.

Employees who have a knowledge of the electrical business, and are capable of answering such technical questions as the public might raise, are absolutely essential. To the degree that we acquire well-informed sales people, just to that degree will we maintain our competition with other merchants.

Read the Trade Papers

Keep posted upon every up-to-date idea. This can only be acquired by reading the trade papers. I would suggest that we consider it almost a religion—the necessity of reading, each morning, for not less than fifteen minutes, some good trade paper. We are more or less deficient in reading the very valuable information available through the medium of the trade press.

Next in importance, in the retail merchandising proposition, comes local newspaper advertising. We must acquire the habit of local newspaper advertising. It should not, in any way, be considered an additional burden, or expense. You cannot successfully conduct a retail store without local newspaper advertising. I would like to see the electrical industry acquire that habit, at a very early date.

The tendency on the part of dealers to argue with cus-

tomers about goods that have proved unsatisfactory is a thing that should be eliminated. I believe we should adopt a slogan that no sale is made unless the customer is satisfied, and freely take back any article that may have proved unsatisfactory to the customer.

We should hesitate to sell to the consumer an article of unknown value to us. Merely because an increased margin of profit is offered is no reason for our selling goods of unknown merit. There are too many articles on the market of known merit, and the tendency on the part of dealers, after a line has been established and a popular demand created, when a new and cheaper line comes on to the market, to take on this new line, should be deprecated.

The public will purchase from electrical people because of the superior knowledge of electrical matters that, they believe, the electrical man possesses. Time alone will prove whether we are utilizing that superior knowledge to the best advantage.

Window Display Dealer's Biggest Asset

Perhaps the biggest asset of a dealer is the window display, which by no means is utilized to the maximum efficiency at this time. Facilities have not been provided to make the proper display, except in a few specialized lines. More important than an extra 5 or 10 per cent. discount is an attractive window display. Urge manufacturers to give you the facilities to display your appliances and materials, and utilize your window display. Follow the experience of the best merchants in your community—the department store. And bear in mind that the selection of the most desirable location in the community is the occasion for window display. A good store, in a good location, is of no value without an attractive window display. That is the biggest asset that you possess once you have established your location, and you should utilize it to its maximum efficiency.

Standard Plugs and Receptacles

The most important item that retards retail development, to my mind, at this time is the lack of standardization of wall, or convenience, receptacles—lack of standardization of plugs and receptacles on current-consuming appliances, such as toasters, flatirons, vacuum cleaners and other devices. That lack of standardization is due, solely, to the petty jealousies of the various manufacturers.

There is no medium that I know of that can enforce standardization of these things, except the contractor-dealer. I would like to see some action taken that would cause the manufacturers of this country to appreciate that they are retarding the growth of the entire industry by their petty jeal-

Practically every one likes to be waited on by a salesman—not a "clerk." He must know his goods and be able to explain them in every-day language.

ousies and selfishness, in trying to put over their pet designs of receptacles.

We must first require a standard receptacle and then back it up with a campaign to rip out every wall receptacle in this country that doesn't fit that standard. Twenty or twenty-five years thereafter we must follow the example set by the manufacturers of incandescent lamps, and then, next, we must do something to enforce, on the part of the appliance manufacturers, interchangeable receptacles. For intelligent men to continue, in these modern times, selling one or more dozen appliances, and requiring the purchaser to

buy a different plug and provide a different receptacle for each one, reflects no credit upon our industry. Each plug and receptacle should be standardized, just as the incandescent lamp has been standardized. What the standard is I care not, and who suffers by the bringing about of such standardization I care not. Even those who may be first to suffer considerable loss in the bringing about of this change would reap their reward in compound interest in a very short time.

Save Time

I would like to see the contractors establish locally "customers' records," so that each consumer may be recorded as to the appliances in use in his home. Much time and a considerable amount of money is being wasted in useless selling and house-to-house solicitation, trying to reach consumers with devices that they have already purchased. In a number of communities in this country careful records are kept through the card system by dealers and central stations, and much time and money can be saved if such a record is kept.

We are wasting much time, and the time of the consumer in campaigns designed to interest them in, for instance, flatirons, when they already have one in use. If we have a knowledge of what the customer possesses, then we will apply intelligent salesmanship, and try to reach them with a device which we might sell to them.

Suggestions for Increasing the Sale of Electric Washing Machines—The Housewife in Average Circumstances is Your Best Prospect

The Society for Electrical Development, in its last issue of "Sales Service," gives some valuable hints on selling electric washing machines, intended to assist the individual contractor-dealer. It is assumed that you have an agency for some one of the many good washers. Having decided to go after the washing machine business, your first move should be to study the field.

What is Your Field?

Into what class will your prospects fall? Bear in mind that it is by no means always the wealthy who are the best prospects. On the contrary this class, being able to afford more servants, are often the poorest prospects. It is really the big middle class, the women who do their own housework, who will most appreciate the advantages of washing electrically. It is interesting to note that only about 15 per cent. of the families in this country employ servants.

Go to your central station and find out where the largest number of new customers are coming from. Is there a new industrial development in your locality?

Consider the real estate men. In one of the new additions in a certain large city electric washers and ranges have been installed in each house by the builders. Flats and apartments, contrary to some opinions, offer excellent opportunities for washer sales.

Classify the prospects, arrange them according to location and financial means and as far as possible group them. You will save your salesman's time and your own money if you concentrate on one district at a time. When you have made one sale in a block work hard on the other prospects in that street.

Never let an inquiry get "cold." When you get a live lead have it followed up promptly even if it is outside the district which you are working at that particular time.

Presenting the Idea

If you employ salesmen get the right kind. Insist on their representing you properly. Down-at-the-heel men are pretty sure to do you more harm than good. We will not

go into the question of training salesmen here, but the manufacturers will be able to help you on that point and the Society will also give you assistance if you need it.

If you do not employ salesmen to any extent you must more than ever, depend upon the mails and other forms of advertising to do the preliminary selling work—to get the prospect up to the point where a demonstration or sale can be arranged.

The idea of washing electrically should be presented to the prospect as a distinct saving. Some women will have to be sold on the advantages of the electric washer, but you will probably find that a large number are already convinced that they would like to have a washer but cannot see how they can afford it. This brings us to the question of "easy payments" and it may be said in passing that the majority of washers will have to be sold on that plan.

The Price

The total selling price of an electric washer appears high—unless it is sold definitely on its performance before price is even mentioned. That price need not be a bar to sales is proven by a glance at some of the other articles which have sold in spite of price;

Kitchen Cabinet vs. Kitchen Table.

Electric Iron vs. Sad Iron.

Electric Cleaner vs. Broom.

The time payment plan should and will solve most of the price difficulties. We will not go into details of the various methods of financing time payment sales. It should be borne in mind, however, that the tendency is to reduce the length of the payment period. The good salesman will make the best terms possible and will often be surprised himself to find that he can get cash in full.

There are not many people, even among those using electric washers, who appreciate the real saving in dollars and cents. Here is an argument which, with care, you can use on most any class of prospect.

Show How Washer Pays for Itself

With Electric Washer

Laundress, 1 day, wash and iron	\$2.00
Her carfare	.10
Her meals, two	.70
Current for washing	.05

Cost with washer

Without Electric Washer

Laundress, 1 day, washing	\$2.00
Laundress, 1 day, ironing	2.00
Her carfare, 2 days	.20
Her meals, 2 per day	1.40
Wear on clothes (approximate)	.50

Cost without washer

Cost with washer

Saving per week

There is a saving in 52 weeks of the year of \$169.00 or more than enough to pay for the washer. It should be noted that the wages of the laundress will be, in many cases, higher than we have placed them.

In this same connection the point should be made that it is often difficult to get a laundress at any price unless an electric washer is used. To the woman who does her own washing it may be necessary to convince her that her own time is worth something. She will save a day of her own time if she uses the electric, to say nothing of the relief from the most disagreeable of household tasks.

Therefore in selling, talk the labor saving (with or without laundress) the clothes saving because there is no rubbing; the time saving, because several pieces are washed at one time; the money saving, because requiring less time.

For every objection to the electric washer there are two

good reasons why the prospect should use it. It is not necessary to give all the reasons here as all manufacturers' literature gives them. If the manufacturer puts out a sales manual see that every one connected with the selling of washers in your organization is familiar with it. You will get other favorable arguments from the users of washers right in your own town.

Efficiency in the Repair Business*

In being asked to take a part in this section meeting I was assigned the subject, "What Constitutes Efficiency in the Repair Business." I accepted this subject with certain reservations as the experience of my company and myself has been a long way from sufficient to have me begin to tell you all that goes to make up efficiency in the repair business, and therefore I believe my subject should be stated more properly as "The Importance of Efficiency in the Repair Business."

In the development of the contractor-dealer's business during the period of reorganization and readjustment since October, 1917, when Wm. L. Goodwin pointed the way to larger fields of endeavor and greater possibilities for us, there has come to many contractors the realization of the opportunities to be had in the sale of used and rebuilt electrical machinery and the repairs of this equipment. I shall not discuss the business of selling used machinery which our company has found profitable, but I want to give you briefly the result of our experience in repairing and rebuilding electrical equipment and to point out to you how important efficiency is in this line of work.

The repair shop of the contractor a very short time ago was not much more than the corner of the stock room. In some cases he had a small room set aside for this work, but the one or two men employed at that time did not appear to him of sufficient importance to provide these men with either the proper place or equipment so that they could make a showing that was at all comparable with the wiring and construction department. Our company passed through this stage of development and then we began to realize that by giving our machinery repair department just a small part of the attention the construction department was receiving that in a short time it began to show real results and looked like a paying proposition. We then turned our attention to the department with the idea that it should become as important a factor to our total business as the construction department. The plan we followed started out with a careful study of the best way to get machinery repair business and the proper way to handle it after we were able to get it. Our plan therefore developed as follows:

How to Get the Business

We found in this connection that three important factors were essential in going after repair business. It was necessary to: 1st, advertise in the local newspapers and the trade papers. The repair business is entirely different from contracting or merchandising in that the average consumer who needs your service has no idea of where he can go to get a good job of repair work done and in the case of the large industrial plant they usually have done their own repair work, or sent it to the repair shop of the manufacturer of their electrical equipment. We found also an excellent advertising medium was a series of letters sent to the customers, enclosing advertising blotters. The third and most important fact in the How to Get the Business Plan we found

to be a good live salesman, whom we sent out to sell what we termed as electrical repair service, and we found by carefully following up our advertising we were able to get business from companies who formerly had told us they were not in the least interested.

A salesman of this service need not call oftener than once a month on the larger plants and once in 60 days on the small plants. By persistently following this plan you can get your share of the repair business in your community. Now that you have the business the next part of the scheme is to be able to handle it properly and efficiently. It is even necessary for you in some cases to give better service, certainly a prompter service than the manufacturers' repair shop, if you expect to hold the business of the plant or customer who has felt he was fairly well taken care of before you sold him. It is therefore of primary importance to have a good organization. You need a manager of the repair department, some one who will be held entirely responsible for the proper handling of the work and this party, may be at the same time your salesman. We found the duties of the manager and salesman combined nicely and worked out much the same as in our construction department where the department manager is responsible for getting all business and supervising the work after we get it. It is necessary also to have a service man who can assist with the purchasing of the repair department materials. Then, most important in your repair shop organization is the foreman of the shop who must be a man of practical and technical experience, a good executive in handling men and a person who is willing to co-operate with your other people. It is necessary also to have a good stock man and a careful accounting and billing department. Promptness and accuracy in sending invoices make the repair business a pleasure because a large part of the work is labor, and all repair business should be handled on a strictly cash basis.

We found further that a most important adjunct to our organization was proper forms for making records of each job we handle and we have developed in the following order a customer work order, the confirming order, the repair shop order, identification tag and shipping tickets. The importance of your organization is in a measure secondary to the proper equipment of your shop. We have found that the right kind of equipment such as coil winding and tapping machines, a baking oven and coil dipping tanks, etc., are an absolute necessity in a shop that expects to be any factor at all in the repair business because without the equipment the work cannot be efficiently handled and if not efficiently handled it is not profitable. It is therefore necessary to invest a considerable sum of money in the proper kind of equipment, and for this reason no contractor should undertake to go into the repair business who has not the capital to make this investment.

I have now briefly outlined what our company has found a necessary part of handling the repair business along efficient lines. There are many details that I have not touched upon which enter into the conduct of the repair business, but I have tried to show you how all important is the matter of efficient organization and equipment to this business.

Griffiths Bros., manufacturers of paints and varnishes, were very busy during the war on Government orders, but are now settling down to cope with the export trade, and have already made several shipments to Canada. During the war the company manufactured for the War Office a new paint for guns that would stand the tremendous heat resulting from incessant firing and that was not affected by corrosive gases and hard weather conditions. This paint is now largely used for commercial purposes, and is a great success.

*A paper presented by Mr. C. T. Jamison, of Milwaukee, at the 19th Annual Convention of Electrical Contractor-Dealers.

An Educational Exhibit

A novel scheme is being tried out by the Van Dorn & Dutton Company of Cleveland, in an endeavor to educate the public, both technical and non-technical, in the value and use of their equipment. Right on a prominent bank corner in the centre of the city this company have obtained permission to place a quantity of their equipment and maintain it in operation in full view of the public. For example, in the photograph shown, spiral bevel-gearing machinery is shown in the actual operation of cutting gears from forged steel blanks. There is also on exhibit an extensive panel board showing various transmissions, differential and timing gears for automobile and tractor use, also miscellaneous spurs, bevels, spirals, wormwheels, racks and

Outdoor display by the Van Dorn & Dutton Company, of Cleveland—Commendable both from an advertising and educational viewpoint

sprockets, etc. It is said that this model demonstration is daily drawing large crowds composed of every class of citizen. It is, evidently, a feature to be commended, both from an advertising point of view for the company and an educational point of view for the citizen.

Seven Cent Fare in Montreal

Montreal tramway fares are again raised, due to an increased wage schedule. The straight fare is advanced from 6c. to 7c., 4 tickets for 25c., instead of five; workmen's tickets, five for 25c., instead of six. The new tariff will give an average fare of 5.8c.

The annual report of the Tramways Commission states that the number of passengers carried during the twelve months was 249,062,211; paying passengers 183,350,928; transfers, 65,711,288; gross receipts per passenger, 3.47 cents; gross receipts per paying passenger, 4.72 cents; receipts per passenger (transportation of passengers only), 4.63 cents; total operating costs and taxes per paying passenger, 3.64 cents.

The report adds: It is interesting to compare the statistics of Montreal traffic during the last four years. It is pointed out that the total expenses of operation and taxes during the fiscal year 1915-1916, which were \$3,707,053 have been augmented during the fiscal year, 1918-1919, to \$6,672,140. In other words an increase of 80 per cent, or nearly three million dollars while the transfer receipts have not increased more than thirty per cent.

The Commissioners in fixing the new fares base their calculations on increased traffic, it being necessary to find

\$12,000,000 to meet all charges during the present fiscal year and to meet a deficit made between February and June this year. The total receipts for last year were \$8,483,137.

Canadian Goods Wanted in England

Mr. F. I. Spielman, of Spielman Agencies, has just returned from a business visit to England, particularly in connection with the firms which he represents on this side. General conditions, he states, are such that it is difficult for manufacturers to make firm quotations and to promise definite deliveries. A great improvement, however, is now in sight, and Mr. Spielman is confident that it will not be long before Great Britain gets down to a satisfactory basis. The industrial unrest after all is not surprising, in view of the upset which resulted from the war. British manufacturers are keen to cultivate business with Canada. Canadian goods are in favor in Great Britain, but they will have to be paid for partly by the purchase of British products.

The British Aluminium Co., for which Mr. Spielman is the representative in Eastern Canada, has made, he said, astonishing development. The company is prepared to take care of all orders for Canada and a large stock is held in the warehouse in Toronto.

The Ward Leonard Electric Company, Mount Vernon, N. Y., manufacturers of Vitrohm, vitreous enamelled, resistor units, lamp dimmers, rheostats and electrical controlling devices, announce the removal of the office of their Philadelphia representative, W. M. Tompkins, from the Commonwealth Building to the Bourse Building Machinery Exhibit, Philadelphia.

Polar Cub Vibrator

The A. C. Gilbert-Menzies Company, Toronto, are distributing to the trade the popular priced Polar Cub vibrator. This vibrator is built around the universal Polar Cub motor, with die cast frame and fitted with cord and plug ready to

use. The motor is nickel plated, the handle being finished in black enamel. Each one is packed in an attractive carton and carries the regular Polar Cub guarantee.

The British Ever-ready Co., after being engaged almost entirely on war work, are getting back to a peace footing, and have increased their equipment. The company has been engaged in developing battery sets for wireless telegraphy and telephony for aeroplanes.

The Canadian Linderman Company, of Woodstock, Ont., who carried on the manufacture of shells extensively during the war, announce that they will commence shortly the manufacture of unit electric light and power systems.

The Shawinigan Water and Power Co. have opened a New York office. The company have also a London branch.

PHILLIPS' ARMOURED CABLES

A detailed cross-sectional view of a three-conductor armoured cable. The central part shows three circular conductors arranged in a triangular pattern. Each conductor contains multiple small, light-colored spheres, representing the conductive strands. The conductors are surrounded by a thick, dark, concentric ring, which is the double steel tape armouring. The outermost layer is a thin, light-colored ring, likely the lead covering mentioned in the text.

Safety Enclosing Cover for Motor Controlling Rheostats

As a result of almost continual widespread "Safety-First" campaigns, the necessity for safeguarding all machinery and those who operate it, is now generally recognized throughout the realm of industry as a matter of vast importance. In the electrical field rapid progress has been made in the past few years in designing new lines of apparatus, redesigning old ones to make the safety feature more prominent, and particular attention has been paid to motor control device because, as a rule, this class of apparatus is handled either by unskilled labor or by those not familiar with electrical machinery, and the necessity for a fool-proof installation is the more obvious. It is interesting to note how the face plate rheostat, manufactured by the Westinghouse Electric and Manufacturing Company, shown in Fig. 1, is protected, and how the enclosing covers are so designed that they can readily be applied to old rheostats to make old installations strictly modern.

As shown in the illustrations the enclosing cover is a solid sheet steel box, which fits tightly against the rheostat base, and is secured by four corner bolts. Pivoted to the cover are two cast iron arms, one with the operating handle

Fig. 1—Rheostat with Face Plate Cover attached

Fig. 2—Rheostat ready to attach cover, showing adapters replacing nuts, and fibre tube replacing handle

on the outside, and one within, made with a fork to engage the rheostat handle. To apply a safety cover to an old rheostat it is only necessary to remove the four nuts on the corner studs of the face plate and replace them with adapter nuts and studs, furnished with the cover. The rheostat handle is also removed and a fiber tube substituted. The cover is then put on so that the fork on the inner arm engages the insulating tube and the four nuts that were on the original rheostat are used to fasten the cover in place. The lead wires from the rheostat are brought through insulating bushings that are held in place by the edge of the cover. While no packing is used to make the cover water-tight, it fits so closely that it effectually prevents the entrance of metal chips, saw dust, or other material that would cause injury to the rheostat. The cover is grounded through the corner bolts and being insulated from live parts, renders it fool-proof and makes it impossible for an operator to accidentally receive a shock through coming in contact with the working parts of the face plate.

The use of these covers or similar devices is one of the important requirements of the modern factory or machine shop, and in some localities it is demanded by law. These covers fulfill all requirements of a safety-first device and are easily and readily installed.

For the ten months ending July 31 the earnings of the Southern Canada Power Co. totalled \$487,847, a gain of \$93,215, or 23.6 per cent. Operating expenses increased \$40,147, or 18.3 per cent. leaving the net earnings at \$228,881, an increase of \$53,067, or 30 per cent.

Current News and Notes

Almonte, Ont.

The Electric Light and Power Commission of Almonte, Ont., have advised the town council to take steps to acquire the Wylie power plant, a privately owned enterprise, as an auxiliary to the plant already owned by the town.

Boston Creek, Ont.

The Northern Ontario Light and Power Company have entered into a contract to supply power to the Miller-Independence Mine where there is being installed new modern mining equipment to be electrically operated. The transmission line will run due east from Boston Creek, following a line half a mile south of the north boundary of the township of Pacaud.

Fredericton, N. B.

Proposals for the incorporation of the St. John Valley Electric Light and Power Company, a new organization, seeking rights in Victoria, York and Carleton counties, have been placed before the New Brunswick legislature. It is understood the new company's plan will be to secure power from the Maine and New Brunswick Power Company's plant at Aroostock Falls; erect pole lines and distribute primarily in the rural districts as well as in the towns and villages in St. John Valley from Perth to Woodstock. These districts are now without electricity, including Kilburn, Bath, Florenceville and Hartland.

Guelph, Ont.

The Wendigo Power Company, with head office in Guelph, Ont., has been incorporated for the purpose of developing hydro power on Wendigo Lake and certain parts of the Blanche River. The plant will be located about 20 miles south of Larder Lake and the ultimate development is given as about 4,000 h.p. The capital stock of the company is \$1,000,000.

Montreal, Que.

Martel & Company, Limited, Montreal, electricians, have been granted a charter.

The Clarke Delorme Electric Supply Company, Montreal, have registered.

Ballard Brothers, electrical supplies, Montreal, Que., have registered.

Smiths Falls, Ont.

A new switchboard is being installed in the Gould plant of the Hydro-Electric Power Commission at Smiths Falls, Ont.

St. Angele, Que.

La Compagnie Electrique de Ste. Angele, Ltd., St. Angele, Quebec, have been granted a charter.

Stratford, Ont.

The new distributing station of the Hydro-electric Power Commission at Stratford, Ont., was opened on August 29.

St. Catharines, Ont.

A Canadian company—a consolidation of the Canadian interests of P. R. Mallory & Co., Inc., the Liberty Electric Corporation and the Abenderoth Company, all of Port Chester, N. Y., and P. G. Nichoff & Company, of Chicago—has leased the factory in St. Catharines operated during the war as a munitions plant by the St. Catharines Machinery, Limited. Tungsten products will be manufactured by the new company.

St. John, N. B.

At a meeting of the directors of the New Brunswick Telephone Company, recently held in St. John, it was decided to ask for an immediate increase in rates.

William Hasbeen

William Hasbeen is in a rut. He HAS BEEN doing the same old things in the same old way for many years. There is as much hope of ever hearing anything new from William Hasbeen as there is hope of the Kaiser joining the Red Cross.

"No," he tells the jobbers' salesmen, "I don't think I want any of those new appliances. I know what my customers want and they are used to my ways. No, I think I'll stick to the old line." If some demonstrator wants to show him a clever selling stunt, or a novel advertising idea, he "hasn't time."

Of course, his trade lops off wonderfully year by year and his old customers go to the progressive up-to-the-minute dealer for their electrical needs.

Some day, a short—a very short—notice will appear in the "just passed away" column of the local Bugle.—Contact.

Cut Connection Costs with

these modern little time and labor saving devices. They have displaced blow torch and solder, they have eliminated trouble and uncertainty in making connections on any interior job.

WALGER CONNECTORS

are passed by the National Board of Fire Underwriters and the Hydro-Electric Power Commission for No. 12 wire and under. They make safe, perfectly insulated and permanent connections; make them quickly, smoothly and efficiently. Use Walgers on your next job and the profit you make will buy you

Walgers for the next half-dozen.

Write for sample, also descriptive folder.

**Walger 2-Way Connector**

For making connections, for lengthening extension wires, and for exchanging fixtures. Simple and convenient.

Chandelier

Outlet Box

Current Tap

Walger 3-Way Connector

To tap feed wires in outlet boxes, in Condulets, or on knob and cleat work. For safe, sure connections.

ESTABLISHED 1849 BRADSTREET'S

Offices Throughout the Civilized
World.

Executive Office:

Nos. 346 and 348 Broadway, New York City,
U. S. A.

THE BRADSTREET COMPANY gathers
information that reflects the financial condi-
tion and the controlling circumstances of every
seeker of mercantile credit. Its business may
be defined as of the merchants, by the mer-
chants, for the merchants. In procuring,
verifying and promulgating information no ef-
fort is spared, and no reasonable expense con-
sidered too great, that the results may justify
its claim as an authority on all matters affect-
ing commercial affairs and mercantile credit.
Its offices and connections have been steadily
extended, and it furnishes information concern-
ing mercantile persons throughout the civilized
world.

Subscriptions are based on the service fur-
nished and are available only by reputable
wholesale jobbing and manufacturing concerns,
and by responsible and worthy financial, fidu-
ciary and business corporations. Specific
terms may be obtained by addressing the com-
pany at any of its offices. Correspondence in-
vited.

THE BRADSTREET COMPANY

Offices in Canada: Halifax, N.S.; Hamilton,

Ont.; Quebec, Que.; St. John, N.B.; Toronto,
Ont.; Vancouver, B.C.; Victoria, B.C.; Win-
nipeg, Man.; Calgary, Alta.; Edmonton, Alta.;
Sydney, N.S.

THOS. IRVING,
Man. Western Canada, Toronto.

A Lost Opportunity

As a wiring contractor, how many times have you turned down orders to repair the Motors or dynamos of your customers and let them send their work to the maker?

How much have YOU lost in prestige through not being able to take care of your customers' business?

How much have YOU lost in Profit on this business?

Get the habit of handling these repairs. Send them to a Specialist in Repairs. Don't send them to the maker. Your customer can do that, and he's already sick of it. The service is too slow. He wants quick work and an absolutely reliable job. You can give it to him.

Make up your mind now. Say "I'm going to get something out of the next repair job in this town."

You have the work of taking out and re-installing the machine (Profit). Send us the machine or part with a description of its action or symptom. We'll rush it through for you, give you an A1 job and you come in again on the Trade Discount (More Profit).

Others are doing it. Why not you? Write about it.

True Recording Instruments

Esterline meters known throughout the technical world for their accuracy and mechanical perfection.

The illustration shows one of the new style Graphic Meters, which is placed in an aluminum case with a glass face. The clock has an eight-day lever movement controlling the chart which is six inches in width and twenty-six feet long. A special inking device has been arranged for the marking of these charts. The holder will contain a supply for eight days. The ink is drawn through the tube to the pen by capillary attraction.

These instruments are ideal for power stations, sub-stations, industrial and isolated plants for recording load curves, voltage, current, and power factor. The value of a true station load curve cannot be overestimated.

NATIONAL PRODUCTS

SHERARDIZED

SHERARDUCT

The Rigid Steel Conduit with both surfaces Sherardized and Enameled. Rust Proof and Acid Proof. Made of a high grade spellerized mild steel tubing.

Write for Bulletin 50

ECONOMY BLACK ENAMELED

ECONOMY Black Enameled Conduit is made of the same high grade spellerized mild steel tubing as **SHERARDUCT**, the only difference being in the protective coating. In an enameled conduit there's none better.

Write for Bulletin 50

FLEXTUBE

Interwoven — Seamless — Non-Collapsible. Inseparable and Double Compounded. Easy to fish and every foot of every coil can be used

Write for Bulletin 151

FLEXTUBE

We cannot tell you *all* about *all* National Products in this limited space, but we want to call your especial attention to certain features of **FLEXTUBE** Double compounded, Non-Metallic Flexible Conduit.

It's the original seamless interwoven non-collapsible, non-metallic flexible conduit with the "roller-bearing" interior. There's absolutely no waste; every foot of every coil can be used, and it's so easy to fish that it's a pleasure for the wiremen to use it. That makes it profitable for the contractor, and its quality is such that the best interests of the owner are served. Note the construction. The seamless interwoven tubing compounded; then the protecting outer braid, also compounded—a double compounded tubing which is satisfying to those who insist upon the highest quality. Place your order for your requirements with your jobber; specify by name—**FLEXTUBE**.

For Interurban Service

For Interurban Service

“Golden Glow”

Ideal for Interurban Service

The various types of “Golden Glow” Headlights for interurban service all project powerful, penetrating, steady, non-blinding beams of “Golden Glow” light—a volume of light actually greater than the average arc headlight projects.

The secret lies in the high efficiency of “Golden Glow” greenish glass reflectors and the general make-up of the headlight through and through.

Therefore when you adopt “Golden Glow” on your cars you are buying headlights scientifically correct in principle and design.

Place your order now, and soon your cars will be headed by beams of cheery “Golden Glow.”

THE "TYPE S" PORTABLE WHEATSTONE BRIDGE

Accurate—Rugged—Inexpensive

In factory or field, the Type S set will quickly and accurately measure resistance or locate faults. It will withstand, without detriment to its electrical qualities, the knocks which such a set is bound to get. It is of the Dial Decade Type, and therefore simple to operate.

Excellent design plus quantity production enables a low price without sacrificing accuracy—ratio coils 1/20 per cent, rheostat coils 1/10 per cent guaranteed.

The removable suspended coil galvanometer deflects a millimeter per microampere. This combination—accuracy of adjustment of coils, sensitivity of indicator, ruggedness, inexpensiveness—is found only in the Type S set.

PRICE \$75.00

CANADIAN CROCKER-WHEELER MOTOR GENERATOR SET.
 MOTOR, 30 H.P., 550 VOLTS, 3 PHASE, 60 CYCLES, 1200 R.P.M.
 GENERATOR, 20 K.W., 110 VOLTS, COMPOUND WOUND,
 INTERPOLE TYPE.

“Made in Canada”—complete

A motor generator set of the highest efficiency it is possible to build anywhere. Motor is of modern Canadian Crocker-Wheeler design with cast-welded end ring construction. Long life there. Generator is of the interpole or commutating pole type which means operation from no load to a heavy overload without sparking and without shifting the brushes. Long life again — absence of shut downs—steady satisfaction.

EUREKA
VACUUM
CLEANERS

There is a well cultivated field for electrical home appliances. Women are putting aside old-fashioned methods that made drudgery of housekeeping. The Eureka Vacuum Cleaner is fast banishing the sweeper where there is electric current, because it is the ideal way of getting all the dirt in a few minutes without labor, without raising dust, and without wearing carpets.

You should be handling the Eureka because it is the ambition of every housekeeper to possess one. Our selling plan will be of particular interest to you and a profitable one for you to link up with. Write for particulars now.

WIREMOLD

NEATLY CONCEALS ALL SURFACE WIRING

An Electrical Necessity

THERE are literally hundreds of people in every district who want electric appliances of different kinds, but who do not have them because there are no convenient receptacles on which to plug in. The tidy housewife may dislike a long cord dangling from the chandelier above her dining room table. Consequently, she has neither electric toaster, percolator, nor grill. Also, she may fully appreciate the beauty and usefulness of a boudoir lamp at her bedside, yet not buy one because it would involve a similar disagreeable arrangement. And this applies to electric irons, washing machines, vacuum cleaners, heating pads, radiators, and all the host of appliances—which you will sell in far greater numbers if you solve this difficulty for your customers. **WIREMOLD IS THE SOLUTION.**

These books and the WIREMOLD advertisements are daily spreading the fame of WIREMOLD. They are beautifully illustrated and contain hundreds of interesting ideas showing WIREMOLD in use. **WRITE FOR YOUR COPIES.**

LOCOMOTIVE

ELECTRIC WASHER

The Masterpiece of Simplicity for Which the Trade and the Housewife Have Been Long Watching and Waiting

The trade will recognize in this machine a type of electric washer which eliminates the many conceded objectionable features of those at present on the market.

The Locomotive Washer is neat, compact, smooth running, quiet, powerful, efficient, economical, reliable and simple, made all of metal, requiring no special wiring.

It is not bulky, cob-webby, or cumbersome, but attractive in appearance. There are no metal or wooden drums to remove or clean. There are no springs or foot rods to dig holes in the linoleum or floor.

In a well braced metal framework sixteen inches wide, four feet long and thirty-one inches high, an oblong copper boiler eight sheet capacity is strapped to a double iron V-shaped track running on grooved rollers, two on each side which carry the weight perfectly balanced of about five buckets of water. A six-inch piston stroke moves the boiler horizontally twice every second, forcing the water twenty-six inches through all the clothes in a form of a figure 8.

The inside of the boiler is smooth with flat bottom under which is located a heater for gas, oil or electric. The rapid motion of the boiling water quickly steams, cleanses and sterilizes the clothes without friction or wear.

The reversible safety swinging wringer can easily be lifted off and put underneath, snugly fitting ironing board then forms a table top. The above equipment, together with a quarter H.P. motor, a gas heater and tube, or oil burner, and copper boiler is the standard. A galvanized boiler costs less and an electric burner more.

Dealers and distributors should write or wire for exclusive territory without delay.

THE LYONS ELECTRIC COMPANY

BRANTFORD - ONTARIO

Sole authorized distributors and licensed

ENGINEERS W A N T E D

One of the largest electrical manufacturing firms in Canada want several capable men for the following positions.

Qualifications

ENGINEERS—Several mechanical or electrical engineers who are ambitious to secure advancement in their profession but who are thoroughly appreciative of the fact that worth while advancement can be secured only by aggressive and thorough application to appointed tasks. In your reply, state age, education and experience.

TELEPHONE ENGINEERS — Applications will be considered from men who can read telephone exchange circuit drawings and have either a good college or correspondence school education. It is preferable but not essential that applicants should have had experience in the design of manual or automatic telephone apparatus or equipment.

Apply to—

Dept. 120—P.O. Box 2040

MONTREAL

SUGGESTIONS to Contractor - Dealers

When wiring buildings don't cut the size of wires to a minimum. Educate your customers to provide spare capacity for the increasing demands which are sure to follow. Show the consumer, say by means of alternative prices, the small cost of providing for future demands in the original installation. Nor does your interest in a customer end when the wiring is completed. He is still a prospective customer, and a satisfied customer is the best advertisement—an unsolicited testimonial, a talking sign, that walks, too!

When wiring residences don't fail to urge an adequate number of outlets, and be sure they are **conveniently located**. A customer may not be sure just what he needs in advance, therefore sound advice is welcomed, and when it works out in practice as you promised, the customer will tell his friends of your ability.

Standardize your outlets. It means efficiency and true economy, which benefits you in the long run.

Are you familiar with all the electrical appliances on the market today? Have you made up your mind the best lines to push? The best sellers?

Do you call at the Hydro Store from time to time to look over appliances of interest to yourself or your customers? We are glad to see you and show you what we have at all times, and investigate any new appliances for you.

The Hydro by co-operation has reduced the cost of electric service to the point where it is available to everyone, and is now recognized as a necessity—not a luxury. The Hydro therefore can fairly claim to be helping you to build up your business.

How many of the 60,000 Hydro users in Toronto are your customers?

Toronto Hydro - Electric System

Available Business for the Electrical Dealer

The rapid progress in electrical development is making the electrical dealers' business one of growing importance with bigger demand upon it every day.

Every modern home now finds electricity indispensable and every industrial plant uses electrical power. There exists, then the opportunity for every electrical dealer to grow with this application of electricity.

The C. G. E. sales plans have been formulated to help the dealer to obtain his full share of this constantly increasing business.

Our National advertising, our dealer co-operation, and the excellence of C. G. E. products are at your service.

The National Name is a Valuable Asset

There is a time worn, but nevertheless true, saying that "well bought is half sold." Show your customers a nationally known product that has won national repute by judicious advertising, supported by meritorious service, and the chance of your customers' acceptance is 100 per cent.

All the C. G. E. lines have Dominion wide popularity, and are manufactured according to the highest standards of workmanship, to give the satisfaction that merits a regular customer every time.

Make the Most of Your Window

Let its appeal to the passerby be an arrestive one—MAKE him look.

There are almost unlimited possibilities in window display, and the old idea of showing a mere accumulation of merchandise has given place to the aim for distinctiveness.

One central idea well presented in your window display will compel attention and cause comment, and that is the kind of publicity that sells not only what you have in your window but what is on your shelves inside your store.

Why not avail yourself of our free service in providing you with attractive window displays? This service includes the work of expert window dressers, material and advice on the means of attracting trade through the medium of your window. Make up your mind now to ask us for further information. We welcome the opportunity to co-operate with you for bigger sales.

Specific Helps that Keep Your Merchandise Moving

Realizing that the demand created by national advertising has to be completed by directing buyers to their local stores, we have concentrated a great deal of our effort on dealer problems. Our policy has been to render the dealer in C. G. E. products every assistance in local advertising to popularize his business in his town or district and to promote in the minds of the public a ready means of associating the dealer's name with our national appeal. This is the co-operation we offer you, in addition to supplying you with products that will live up to our claims in every respect. Shall this service be yours?

ABOLITES

**Give the Utmost
Effectiveness to
Lighting**

Holder Socket, Diagonal
Type Abolite

Constructed on scientific principles to direct all the light where needed, and to insure efficiency of illumination with the most economical use of current. Abolites are essential to all kinds of industrial lighting. They eliminate glare and make it possible to produce as good work by night as by day.

The holder sockets are well ventilated with best heat radiation.

The different types of Abolites furnish a design for every lighting require-

Shade Holder, Bowl Type
Abolite

ment. They are easily installed and the cost of their maintenance is down to a minimum.

Abolites are all porcelain enamelled in the A-B. Company's own porcelain enamelling plant. The A-B. finish is uniform in structure and will not crack.
